INDEX.

NAME INDEX.

Abbot (Dr. C. G.), The Earth and the Stars, 819

Abel (Prof. J. J.), awarded the annual award of the Research Corporation of New York, 26; Crystalline Insulin, 575

Abel (O.), An Attempted Solution of the Flysch Problem, 367

Abetti (Prof. G.), and others, Spedizione italiana de Filippi nell' Himàlaia, Caracorùm e Turchestàn Cinese (1913–1914). Serie I: Geodesia e geofisica. Vol. I: Astronomia geodetica, geodesia e topografia, 222

Abolin (L.), Influence of Chemicals on the Colour Changes of Fishes, 574

Abonnenc (L.), Drops formed in an Electric Field, 810

Abraham (R. M.), Surveying Instruments: their Design, Construction, Testing and Adjustment, 714

Absalom (H. W. L.), Magnetic Storm of February 23-25, 1926, 416

Adam (A. T.), Wire-Drawing and the Cold Working of Steel, 718

Adam (N. K.), and G. Jessop, The "Gas Laws" in Surface Solutions, 484; The Spreading of Solids on Water Surfaces, 180; The Structure of Thin Films. Part VII, 179

Adams (E. D.), presented with the John Fritz gold medal, 565

Adams (H. C.), The Collection and Utilisation of Small Water Supplies for Rural Communities and Single Houses, 698

Adeney (W. E.), On the Rate and Mechanism of the Aeration of Water under Open-air Conditions, 642; and Miss B. B. Dawson, The Estimation of Organic Matter by means of Potassium Bichromate and Sulphuric Acid, 438

Agar (Prof. W. E.), Trial and Error in the Behaviour of certain Arthropoda, 99

Aitken (A. C.), On Bernoulli's Numerical Solution of Algebraic Equations, 878; On the Theory of Graduation, 70

Aiyar (B. R. Rajam), Rambles in Vedânta: Being a collection of his contributions to the *Prabuddha Bhârata*, 1896–98, 853

Aladjem (R.), Salinity of Nile Water, 871

Albright (W. F.), Painted Pottery from Mesopotamia, 464

Aldrich-Blake (Dame Louisa), [death], 58

Alexander (Prof. S.), Science and the Modern World, 847

Alexander (T.), The Scientific Construction of the Regular Heptagon with Angles correct to Ten Seconds, derived from two Crossed-Parallelograms of a Semi-Ellipse, 466

Ali (Mohammed), Studies on *B. ægypticus*, Pt. 1, 537

Alkins (W. E.), Influence of the Metallic Contact between the Component Wires upon the Electrical Resistance of a Stranded Conductor, 401

Allbutt (Sir T. Clifford), Arteriosclerosis: a Summary View, April 3, Suppt., 18

Allen (C. E.), The Direct Results of Mendelian Segregation, 402

Allen (Sir Harry Brookes), [death], 731

Allen (Prof. H. S.), Haas's Theoretical Physics. Vol. 2, 687

Allis (E. P.), Morphology of Fishes, 837

Alliston (S. K.), The 'Selective Reflection' of X-rays by Crystals of Potassium Bromide, 743

Allmand (Prof. A. J.), and R. H. D. Barklie, The Influence of Alternating Currents in the Electrolytic Corrosion of Iron, 437

Allorge (P.), The Variations of the Hydrogen Ion Concentration in some Sphagnum Peats in the Centre and West of France, 254

Alston (R. L.), Some Developments in the X-ray Analysis of Single Crystals, 34; The Distortion of Large Aluminium Crystals at Crystal Boundaries, 34

Alty (T.), Some Phenomena occurring at the Surface of Bubbles in Water, 180

Amaral (Dr. A. Do), A General Consideration of Snake Poisoning and Observations on Neotropical Pit-Vipers, 297

Anderson (Prof. J.), The bicentenary of the birth of, 242

Anderson (Dr. W.), The Physical Nature of the Solar Corona, 27

André (E.), The Oils of the Chaulmoogra Group, 219

Andrew (J. H.), M. S. Fisher, and J. M. Robertson, Some Physical Properties of Steel and their Determination, 180

Andrewes (Miss Ursula), Dr. Ann C. Davies, and Prof. F. Horton, The Soft X-ray Absorption Limits of certain Elements, 179

Andrews (H. E.), Carabid Beetles from the Kumaon-Tibetan Frontier, 602

Andrieux, The Electrolysis at a High Temperature of Oxides dissolved in Boric Acid or in Borates, 290

Anrep (Dr. G. V.), appointed reader in physiology at University College, London, 362

Anson (F.), The Chinese Point of View, 278

Appell (P.), The Arithmetical Nature of Euler's Constant, 774

Appleton (Prof. E. V.), R. A. Watson Watt, and J. F. Herd, On the Nature of Atmospherics. II., 841

Arber (Dr. Agnes), Monocotyledons: a Morphological Study, April 3, Suppt., 20

Archer (R. M.), The Evaporative Losses of Vacuum-jacketed Vessels of the Dewar Type, 573

Archibald (Prof. R. C.), Abraham de Moivre, 551, 894

Argand (E.), La tectonique de l'Asie, 863

Armellini (G.), An Apparent Oscillation of the Solar Diameter, 71; Measures of the Sun's Diameter, 566; Theory of the Flying Shadows in Solar Eclipses, 181

Armstrong (Dr. E. F.), Dyestuffs, 676

Armstrong (Prof. H. E.), Alice in Wonderland at the Breakfast Table, 166; Bigamous Hydrogen—a Protest, 553; Carbon and Silicon: the two Foundation Stones of the World, 683; Do we—don't we—what do we—know? 195; Ozone and the Upper Atmosphere, 452; Wasteful Research? 823; What we know, 590

Arndt (Prof. K.), translated by W. H. Patterson, A Summary of Physical Chemistry, 412

d'Arsonval, Electrical Accidents and Artificial Respiration, 254

Arthur (J. C.), Grass Rusts of South America, 28

Asahara (G.), Structure of Graphite, 359

Asbrand (Dr.), [death], 97

Asklund (Dr. B.), The Enstatite-Augite Series of Pyroxenes, 136

Aslin (Mary S.), Rothamsted Experimental Station Library. Catalogue, 751

Asplund (B.), Minor Planets, 802

Aston (Dr. F. W.), The Isotopes of Sulphur, 893
Athanasiu (J. A.), The Use of Mixtures of Water and Alcohol in the Electrometric Study of Reactions by Precipitation, 439
Atkins (D.), On Nocturnal Colour Change in the Pea-crab (*Pinnotheres veterum*), 115
Atkinson (Ll. B.), address to the British Electrical and Allied Industries Research Association, 369
Aubert (M.), and E. Aubrée, An Extension of the Method of Critical Solubility Temperatures for the Analyses of Petrols, 471
Audibert (E.), The Mechanism of the Fusion of Coal, 366
Auerbach (Prof. F.), Physik in graphischen Darstellungen. Zweite Auflage, 227; translated by H. C. Booth, Modern Magnetics, 887
Austen (Major E. E.), The House-fly: its Life-history, etc. Second edition, 906
Austin (L. W.), Transmission Formula for Radiotelegraphy, 838
Aversenq, Jaloustre, and Maurin, The Development of *Ricinus communis* in a Culture Medium rendered Radioactive by the Addition of Thorium-X, 611
Aves (O.), The Significance and Detection of Low Errors of Refraction, 400
Ayrton (Hertha), 1854–1923: a Memoir, Evelyn Sharp, 782

Babák (Prof. E.), [death], 902
Bacharach (A. L.), The Determination of Moisture, Calcium and Phosphorus in the Bones of Rats, 470
Bachrach (Mlle. Eudoxie), Effects of the Intoxication of the Lactic Bacillus by Potassium Chloride at different Temperatures, 810
Backhurst (I.), Obliquity Corrections in Radium Estimation, 609
Bailey (C. W.), The Professor on the Golf Links: some Sidelights on Golf from Modern Science, 585
Bailey (E. B.), Structural Features of the Earth, 863
Bailey (J. W.), Loring Woart Bailey: the Story of a Man of Science, 886
Bailey (Dr. L. H.), elected president of the American Association and of the Botanical Society of America, 286
Bailey (R. W.), H. J. Tapsell, and J. Bradley, 'Creep' in Metals, 636
Bailey (S. and J.), The Discovery of Concealed Coal, 495
Bainbridge and Menzies' Essentials of Physiology. Fifth edition, edited and revised by Prof. C. Lovatt Evans, 372
Baker (C.), Catalogue of Second-hand Scientific Instruments, 392
Baker (H. B.), Anatomy of Hendersonia, 464
Baker (Prof. H. B.), nominated as president of the Chemical Society, 207; and Prof. J. Thorpe, The Taxation of Research, 859, 894
Baker (Prof. H. F.), Principles of Geometry. Vol. 4: Higher Geometry, 149
Baker (T. Thorne), The Sensitivity of Selenium Cells, 858
Baker (W. M.), and A. A. Bourne, A School Geometry on "New Sequence" Lines, 12
Bakke (A.), and Paula Henegger, The Polarimetric Determination of Sucrose in Condensed Milk, 809
Balbi (C. M. R.), Loud Speakers, their Construction, Performance and Maintenance, June 12, Suppt., 47
Baldet (F.), V. Burson, and H. Grenat, The Magnetic Storm and the Aurora Borealis of April 14, 1926, 774
Baldwin (O. R.), and Prof. G. B. Jeffery, The Relativity Theory of Plane Waves, 363; Electronic Orbits on the Relativity Theory, 363
Baldwin (S.), Address at opening of the Optical Convention, 562
Balfour (Earl of), and others, Science, Religion and Reality, 479; to deliver the Messel Memorial Lecture, 169
Balfour-Browne (F.), appointed professor of entomology in the Imperial College of Science and Technology, 535; Concerning the Habits of Insects, April 3, Suppt., 19
Ball (Sir Robert Stawell), A Popular Guide to the Heavens: a Series of Eighty-six Plates; with Explanatory Text and Index. Fourth edition, completely revised and edited by Rev. T. E. R. Phillips, April 3, Suppt., 21
Ball (W. W. Rouse), bequest to Cambridge University, 912
Balls (Dr. W. L.), and H. A. Hancock, Measurements of the Reversing Spiral in Cotton Hairs, 217
Balme (H.), Educational Progress in China, 564
Bandulska (Helena), On the Cuticles of some Fossil and Recent Lauraceæ, 609
Banerji (B. B.), The Electrode Capacity and Resistance of Electrolytes for a Wide Range of Frequencies, 252
Banta (Dr. A. M.), A Maleless Race of Daphnia which produces Ephippial Eggs, 803; The Absence of an Innate Sexual Cycle in Cladocera, 804
Barcroft (Prof. J.), elected to the chair of physiology in Cambridge University, 32; Organs of Multiple Function: The Spleen, 632; The Respiratory Function of the Blood. Part I.: Lessons from High Altitudes, 747
Bardelli (Prof. P.), Estimation of Anti-Tetanic Serum, 671
Barker (Prof. B. T. P.), and O. Grove, The Preservation of Fruit, 100
Barkla (Prof. C. G.), Light Quanta and Photo-electric Emission, 448; and Dr. S. R. Khastgir, The 'Modified Scattered' X-Radiation, 228
Bartels (J.), On the Determination of Minute Periodic Variations, 437
Bartlett (Capt. R. A.), awarded a Daly medal of the American Geographical Society for 1925, 60
Barton (Prof. S. M.), [death], 596
Barton, Jr. (Prof. W. H.), and Prof. L. H. Doane, Sampling and Testing of Highway Materials, 650
Bartsch (Dr. P.), Dr. Pilsbry, and Prof. T. D. A. Cockerell, New Mexican Land Shells, 431
Basedow (H.), Leading an Expedition to the Northern Territory, Australia, 764
Bassett (Dr. H.), The Theory of Quantitative Analysis and its Practical Application, April 3, Suppt., 24
Bateson (Dr. W.), [death], 239; [obituary article], 312
Bateson (Dr. W. and G.), Colour Variations in Partridges, 173
Bather (Dr. F. A.), Dr. W. E. Hoyle, 277; elected a foreign member of Die Kaiserliche Deutsche Akademie der Naturforscher zu Halle, 317; elected president of the Geological Society of London, 355; References and Re-paging of Reprints, 516; The Geological Congress and Museums, 199
Bathurst (Earl), The Breeding of Foxhounds, June 12, Suppt., 42
Baxandall (F. E.), Nitrogen in the Sun and Stars, 483
Baxter (G. P.), and H. W. Starkweather, The Density and Atomic Weight of Helium (II.), 402
Bayeux (R.), Hæmatolysis and Hæmatopoiesis at very High Altitudes and in Air experimentally rarefied, 254
Baykoff, The Theory of Hardening of Hydraulic Cements, 290
Bayzand (C. J.), The Palæolithic Drawing of a Horse from Sherborne, Dorset, 233
Beall (Miss Sarah), Astronomic Determinations by United States Coast and Geodetic Survey and other Organizations, 140
Beals (C. S.), Quartet Terms in the Arc Spectrum of Copper, 324
Beaver (C. J.), Insulated Electric Cables. In 2 parts. Part I.: Materials and Design, 852
Becher (Prof. S.), How to Use the Microtome. Third edition, 392
Becker (Dr. A.), The Velocity of Secondary Cathode Rays, 100
de Beer (G. R.), The Organisation of the Embryo, 706
Beers (C. D.), Encystment in Didinium, 357
Bell (A.), [obituary article], 130
Bell (Sir Hugh), awarded the Bessemer gold medal of the Iron and Steel Institute, 565
Bell (J.), The Constitution of Dicyanodiamide, 642
Bellamy (F. A.), International Phenology, 658
Belling (Dr. J.), On the Occurrence of $2n+1$ and other Chromosomal Mutants, 693
Bemporad (A.), A New Method of Studying Experimental Results, 643
Benn (Eng.-Capt. E. P. St. John), appointed a Naval A.D.C. to the King, 492
Benson (W. A. S.), Drawing: its History and Uses, with a memoir by the Hon. W. N. Bruce, 688
Berger (Dr. R.), Die Schalltechnik, 619

Berkeley (C.), The Crystalline Style and Anaerobic Respiration, 518

Berland (L.), Faune de France, 10 : I, 511

Berry (A. J.), Direct Titration of Thallous Salts by Potassium Iodate, 401; Volumetric Analysis: with a chapter on Simple Gravimetric Determinations. Third edition, 619

Berry (E. W.), An Upper Cretaceous Flora, 804

Berry (Dr. E. W.), The Origin of the Banana in America, 210

Bert (L.), and P. C. Dorier, A Complete Synthesis of Thymol starting from Isopropyl Alcohol, 255

Berthelot (D.), address at the centenary celebration of the publication of Carnot's Tract, 494

Berwick (Dr. W. E. H.), appointed professor of mathematics at the University College of North Wales, 741

Besant (Dr. W. H.), and A. S. Ramsey, A Treatise on Hydromechanics. Part I.: Hydrostatics. Ninth edition, 718

Besson (L.), The Influence of the Temperature of one Month on that of the following Month, 611

Best (C. H.), On the Effect of Insulin on the Dextrose Consumption of Perfused Skeletal Muscle, 142; Dr. H. H. Dale, J. P. Hoet, and H. P. Marks, Oxidation and Storage of Glucose under the Action of Insulin, 678; J. P. Hoet, and H. P. Marks, The Fate of the Sugar disappearing under the Action of Insulin, 678

Best (E.), The Maori as he was: a brief Account of Maori Life as it was in pre-European Days, 42; Maori Agriculture, 283

Bews (Prof. J. W.), Plant Forms and their Evolution in South Africa, 583

Beyer (A.), Traumatropic Curvatures in Plants, 358

Bezssonoff (N.), The Rapid Preparation of Mono-molybdophosphotungstic Acid, 919

Bhatnagar (Prof. S. S.), and R. B. Lal, Effects of Polarised Light on Bacterial Growth, 302

Bhattacharya (D. R.), The Swim Bladder of some Indian Fishes, 701

Bhore (J. W.), The Forest Research Institute at Dehra Dun, 424

Bichowsky (F. R.), and H. C. Urey, A Possible Explanation of the Relativity Doublets and Anomalous Zeeman Effect by Means of a Magnetic Electron, 575

Bidwell (Dr. P. W.), and Prof. J. I. Falconer, History of Agriculture in the Northern United States, 1620–1860, 506

Billon (P.), Combinations of Oximes with Zinc Chloride, 471; The Reduction of Oximes by Sodium and Absolute Alcohol, 538

Birge (Prof. R. T.), The Energy Levels of the Carbon Monoxide Molecule, 229; The Energy Levels of the Nitrogen Molecule, 81; The Structure of Molecules, 300

Birmingham (Bishop of), appointed Gifford Lecturer for 1926–28, 177; presidential address to the Science Masters' Association, 103; Science and the New Humanism, 110

Birtwistle (G.), The Quantum Theory of the Atom, June 12, Suppt., 46

Bishop (L. R.), appointed a Frank Smart student in botany in Cambridge University, 435

Bjerknes (Prof. V.), The Temperature of Sunspots, 463, 538

Bjerrum (N.), Studies on Ion-association (1), 775

Blake (E. G.), Enemies of Timber: Dry Rot and the Death-Watch Beetle, in which the Origin and Life-history of the two worst Enemies of Timber are given, with a Description of the Damage they cause and the Methods to be adopted for their Examination, 581

Blakely (W. F.), The Flora of N.S.W., 36

Blanc (G.), and J. Caminopetros, Some Experiments on Anthrax Infection, 810

Blanchard (W. O.), and others, Geography of Wisconsin, 394

Blathwayt (T. E.), Discovery of a New Comet, 171

Blau (Fraulein M.), The Photographic Action of H-Rays from Paraffin and Aluminium, 29

Bles (Dr. J. E.), bequest to Cambridge University, 840

Bloch (L. and E.), A Second Spark Spectrum of Iron, 810; and G. Déjardin, A Second Spark Spectrum of Neon, 538

Blom (Dr. A. V.), A Lead Pigment as a Rustless Coating of Iron, 763

Bluh (Dr. O.), Dielectric Constants, 872

Blum (G.), Penumbral Lunar Eclipses, 463

Boas (Prof. F.), Contributions to the Ethnology of the Kwakiutl, 619

Bodding (Rev. P. O.), The Santals and Disease, 499

Boeseken (Prof. J.), translated by Dr. S. Coffey, The Configuration of the Saccharides. 2 parts, 227

Bogert (M. T.), and H. B. Corbitt, Researches on Thiazoles (X.), 182

Bogitch (B.), Concerning the Granulation of Scoria and of Metals, 915; Iron-iron Sulphide Alloys, 327

Bogoiavlensky (L. N.), Penetrating Cosmic Radiation, 805

Bohle (Prof. H.), Electrical Photometry and Illumination: a Treatise on Light and its Distribution, Photometric Apparatus and Illuminating Engineering, 718

Bohr (Prof. N.), Spinning Electrons and the Structure of Spectra, 265

Bolkay (Dr. St. J.), An Arctic Fish in Bosnia, 136

Bolton (E. R.), and K. A. Williams, A Test for Tung Oil, 641

Bonacina (L. C. W.), Climate and Man in the United States, 442; Greenland or Polar Front? 451; The Real Meaning of the New Conception of Time, 556; Wordsworth's Interpretation of Nature, 304

Bone (Prof. W. A.), D. M. Newitt, and D. T. A. Townend, Gaseous Combustion at High Pressures. Pt. VI., 324; F. R. Weston, R. P. Fraser, and D. M. Newitt, New Experiments upon the Combustion of Well-dried Carbon Monoxide and Oxygen Mixtures. Pts. I and II., 324; and R. Quarendon, Researches on the Chemistry of Coal. Part 4, 250

Borthwick (Dr. A. W.), appointed professor of forestry in Aberdeen University, 288

Bosch-Gimpera and L. Pericot, The Prehistoric Cultural Provinces of the Iberian Peninsula, 245

Boschma (Dr. H.), Corals and Zooxanthellæ, 245

Bose (D. M.), Valence Theories and the Magnetic Properties of Complex Salts, 84

Bose (Sir Jagadis C.), conferment upon, of the Ordre de Léopold, 765; The Action of Cobra Venom on Plants, 834

Bose (Prof. S. R.), Luminous Leaves and Stalks from Bengal, 156

Bosman (L. P.), The Hydrolytic Properties of certain Amino-acids, 70

Bottomley (Dr. J. T.), [death], 731; [obituary article], 830

Boulenger (E. G.), The Aquarium Book, June 12, Suppt., 41

Boutaric (Prof. A.), La lumière et les radiations invisibles, 853

Bouvier (Prof. E. L.), elected an associate of the Royal Academy of Sciences, etc., of Belgium, 26

Bowen (J. T.), Dairy Engineering, 151

Bower (Prof. F. O.), A Scheme of Phyletic Grouping of Ferns, 437; awarded the Neill Prize of the Royal Society of Edinburgh, 699

Bowie (W.), Isostasy in the Southern Pacific, 246; and others, Isostasy in Western Siberia, 395

Bowyer (W.), The New Greenwich Sidereal Clock, 98

Bracelin (P.), The Period of Decay of RaB and RaC, 253

Brachet (Prof. A.), elected a member of the Royal Academy of Sciences, Letters and Arts (Scientific Class) of Belgium, 868

Bradford (Sir John Rose), elected president of the Royal College of Physicians, 565

Bradley (A. J.), and E. F. Ollard, Allotropy of Chromium, 122

Bradshaw (J. G.), Geometry for Beginners, as far as the Theorem of Pythagoras, 79

Bragg (Sir William), The Work of the Davy Faraday Research Laboratory, 167

Bragg (Prof. W. L.), and G. B. Brown, The Crystalline Structure of Chrysoberyl, 180; and J. West, The Structure of Beryl, $Be_3Al_2Si_6O_{18}$, 913

Brainard (Brig.-Gen. D. L.), awarded a Daly medal of the American Geographical Society for 1925, 60

Brame (Prof. J. S. S.), Motor Fuels, 30

Brammall (Dr. A.), Gold in the Dartmoor Granite, 670; Primary Gold and Silver in the Dartmoor Granite, 320

Brancker (Air Vice-Marshal Sir W. Sefton), Air Transport (Gustave Canet Memorial Lecture), 698

Brauner (Prof. B.), elected an honorary member of the American Chemical Society, 808; Prof. K. Lhoták, 561

Braunholtz (H. J.), Stone Implements from Nigeria, 464

Brauns (Prof. R.), Mineralogie, April 3, Suppt., [illegible]1

de Bray (M. Gheury), Domestic Lighting and Heating, 198

Breislak (Prof. S.), the centenary of the death of, 242

Brett (G. F.), and Prof. R. Whiddington, The Passage of Electrons through Small Apertures, 365

Brewer (R. W. A.), The Economics of Carburetting and Manifolding: Vaporising and Distributing Liquid Fuel in a Motor Car Engine, June 12, Suppt., 48

Bricout (P.), The Production of Ultra-Violet Light by the Impact of Electrons of Low Velocity on the Surface of a Metal, 327

Bridel (M.), and C. Béguin, The Application of the Biochemical Method of Research to the Glucosides undergoing Hydrolysis by Rhamnodiastase to the Study of the Fresh Roots of *Polygonum cuspidatum*, 291; and C. Charaux, The Biological Method of Research, in Plants, on Glucosides hydrolysable by Rhamnodiastase, 254; The Ferment extracted from the Seeds of various Species of Rhamnus or Rhamnodiastase, 218

Bridgman (Prof. P. W.), Certain Physical Properties of Single Crystals of Tungsten, Antimony, Bismuth, Tellurium, Cadmium, Zinc, and Tin, 569; Liquid Viscosity under Pressure, 737

Brieger (F. G.), and A. J. Mangelsdorf, Linkage between a Flower Colour Factor and Self-sterility Factors, 811

Brière (Mlle. Y.), The Existence of Uraninite (Pitchblende) in certain Pegmatites from Madagascar, 574

Briers (F.), D. L. Chapman, and E. Walters, Intensity of Illumination and Photochemical Change, 805

Briggs (G. E.), reappointed demonstrator in plant physiology in Cambridge University, 177

Briggs (G. H.), A Photographic Method of determining the Mobility of Recoil Atoms, 34

Briggs (Prof. H.), The Wheatstone Bridge as the Means of measuring Linear and Angular Dimensions at a Distance, and its Application to Borehole Surveying, 365

Brigham (Dr. W. T.), [death], 459

Brillouin (M.), Is the Moon Radioactive? 642

Brinkworth (J. H.), The Ratios of the Specific Heats of Nitrogen at Atmospheric Pressure and at Temperatures between 10° C. and −183° C., 325

Brioux (C.), and J. Pien, The Comparative Fertilising Action of the Different Forms of Nitrogen existing in the New Ureic Nitrogenous Manures derived from Cyanamide, 402

Briscoe (Prof. H. V. A.), and P. L. Robinson, The Constancy of Atomic Weights, 377

British Drug Houses, Ltd., A Soil Testing Outfit, 392

Briton-Jones (Dr. H. R.), appointed professor of mycology in the Imperial College of Tropical Agriculture, 535

Brodetsky (Prof. S.), The Equations of the Gravitational Field in Orthogonal Co-ordinates, 365

de Broglie (M.), and Dr. A. Dauvillier, The Compton Effect, 321; and J. Thibaud, The Total Reflection and Variation of the Refractive Index of the X-rays in the Neighbourhood of an Absorption Discontinuity of the Mirror, 218

Bronn's (Dr. H. G.), Klassen und Ordnungen des Tierreichs wissenschaftlich dargestellt in Wort und Bild. Sechster Band, Abt. 1, Lief. 39; Fünfter Band, Abt. 2, Lief. 100; Dritter Band, Buch 2, Lief. 147, 511

Brooks (C. E. P.), Pressure Distributions associated with Wet Seasons in the British Isles, 809; The Meteorological Conditions during the Glaciation of the present Tropics, 641; The Variation of Pressure from Month to Month in the Region of the British Isles, 642

Brooks (Dr. C. F.), The Atmosphere and Human Comfort, 528

Brooks (F. T.), and W. C. Moore, Silver Leaf Disease, 736

Broom (Dr. R.), The Boskop Skull, 589

Brown (A.), An Extension of Ceva's Theorem to Polygons of any Number of Sides, 70

Brown (E. T.), The Book of the Light Car, June 12, Suppt., 47

Brown (Prof. E. W.), The Effect of Varying Mass on a Binary System: a correction, 402

Brown (Prof. G. B.), elected a member of the Athenæum Club, 207

Brown (Dr. H. P.), An Elementary Manual on Indian Wood Technology, June 12, Suppt., 43

Brown (Miss Ida A.), Geology of the Milton District, 107; Some Tertiary Formations on the South Coast of N.S.W., with special reference to the Age and Origin of the so-called "Silica" Rocks, 142

Brown (Dr. W.), and Prof. G. H. Thomson, The Essentials of Mental Measurement. Third edition, 374

Browne (Prof. E. G.), [death], 94

Browning (Prof. C. H.), Bacteriology, 79

Browning (F. R.), Modifications in the Calyx of Primula, 702; Phyllody in the Primrose Flower, 518

Brownlie (D.), Manufacture of Smokeless Fuel, 769

Brownson (T. K.), and F. M. Cray, Conductivities of Hydrogen and Potassium Chloride, 211

Bruhat (G.), and M. Pauthenier, The Rotatory Power in the Ultra-Violet of Tartaric Acid in Dilute Solution, 810

Brun (B.), The Properties of Ternary Liquid Mixtures, 915

Bruni (G.), and A. Ferrari, Solid Solutions between Compounds of Elements of different Valency, 367

Bruzs (B.), Thermodynamic Derivation of a Black Body Radiation Isotherm, 811

Bryan (Prof. G. H.), Diatoms and Flocculent Matter, 519; The Mathematical Tripos, 198

Buckley (O. E.), and L. W. McKeehan, Magnetic Properties of Permalloy, 838

Budge (Sir E. A. Wallis), The Mummy: a Handbook of Egyptian Funerary Archæology. Second edition, 407

Buisson (H.), and C. Jausseran, The Ozone Variations of the Upper Atmosphere, 327

Bull (P. G.), Marvels of Sound, Light and Electricity: an Introduction to some Physical Phenomena for Young Students, June 12, Suppt., 45

Bulman (H. F.), and Sir R. A. S. Redmayne, Colliery Working and Management: comprising the Duties of a Colliery Manager, the Superintendence and Arrangement of Labour and Wages, and the different Systems of Working Coal Seams. Fourth edition, 687

TITLE INDEX.

Aberdeen University: approval of ordinances for the establishment of chairs in Forestry and Bacteriology; the Bishop of Birmingham appointed Gifford Lecturer for 1926–28, 177; appointments in, 288; honorary degrees to be conferred on Prof. F. W. Oliver, Dr. R. W. Reid, and Prof. T. B. Wood, 362; appointments; a post-graduate course in the faculty of medicine to be instituted, 435; conferment of degrees, 501; Dr. A. W. Downie appointed Georgina McRobert lecturer in pathology, 876
Absorption and Resonance Radiation in excited Helium and the Structure of the 3889 line, W. H. McCurdy, 811
Accidents, The Human Factor in, Miss Newbold, 701
Acenaphthene, The Oxidation of, R. Marquis, 915
Acetic: Acid, Glacial, The Analysis of, H. Droop Richmond and E. H. England, 641; Anhydride, The Analysis of, H. Droop Richmond and J. A. Eggleston, 641
Acetone in the gaseous state, the thermal decomposition of, a homogeneous unimolecular reaction, C. N. Hinshelwood and W. K. Hutchison, 469
Acetylene, the Action of Acrolein on the mixed Dimagnesium derivative of, Lespieau, 574
Achievement, Aptitude and, Prof. J. McKeen Cattell, 87
Actinium Series: The, and the Lead Ratios in Rocks, Prof. T. R. Wilkins, 719; The γ-Radiation of the, Fräulein L. Meitner, 137
Activated Molecules in a Chemical Reaction, Evidence for the existence of, O. R. Wulf, 575
Adaptation, L', Prof. L. Cuénot, 447
Adélie Land, Magnetite Garnet Rocks from, A. L. Coulson, 210
Administration, Statistics in, 37
Adolescence, The Relation of Weight to Height during, D. Caradog Jones, 515
Adsorption, Theories of, and the Technique of its Measurement, Prof. J. W. McBain, 550
Adult Education, The place of the Local College in, Prof. Peers, 434
Ægean Civilisation, The, Prof. G. Glotz, 716
Œnothera, The third Linkage Group in, G. H. Shull, 181
Aerial Colloids; Smokes as, Prof. A. Whytlaw-Gray, 201
Aerofoil for two-dimensional Flow, On the Drag of an, A. Fage and L. J. Jones, 842
Aeronautical Research, The Relationship of Physics to, H. E. Wimperis, 860
Aeronautics, gift for research, etc., in, in America, D. Guggenheim, 133
Africa, Economic Concepts in, Prof. Muntz, 239
African Elephant: On some Strongylid Nematodes of the, H. O. Mönnig, 742; The Anatomy of the Head of a Fœtal, N. B. Eales, 538
Agricultural: Atlas of England and Wales, An, made on behalf of the Agricultural Economics Research Institute, University of Oxford, J. P. Howell, 408; Education in the United States, 175; England and Wales, 408; Progress in the United States, 506
Agriculture: and Fisheries, Ministry of, Report of the Work of the Intelligence Department of the Ministry for the years 1921–24, 73; Insect Pests in, The Control of, Dr. A. D. Imms, 248; Research and Education in, 73
Air: -flow, Measurement of, E. Ower and F. C. Johansen, 285; Gas Ratio in Gas Burners, 641; -ship, The Rigid, a Treatise on the Design and Performance, E. H. Lewitt, 299; Survey, Some Precision Problems in, Lieut. M. Hotine, 106; Temperature in the Arctic, Dr. H. U. Sverdrup, 838; Transport, Air Vice-Marshal Sir W. Sefton Brancker (Gustave Canet Memorial Lecture), 698
Alaska, A Giant Crater in, W. R. Smith, 359
Albino Mouse, The Œstrous Cycle of the, A. S. Parkes, 877
Alchemical: Manuscripts, Italian, E. J. Holmyard, 544; Secret Names, E. Wiedemann and J. Ruska, 174
“Alchemistische Decknamen,” E. J. Holmyard, 155
Alcohols: Aromatic, The Etherification of the, J. B. Senderens, 574; Tertiary, The Ketonic Splitting of the, V. Grignard and F. Chambret, 366
Aldehydes, The Absorption of the Ultra-violet Rays by, S. A. Schou, 775
Alert Expedition: Polychæta of the, families Hesionidæ and Nereidæ, C. C. A. Monro, 437
Aleutian Islands, Archæology of the, W. Jochelson, 283
Algebraic Numbers and Division, The, Dr. J. C. Fields, 396
Algol Variable, Another, J. Witkowski, 244
“Alice in Wonderland at the Breakfast Table,” Prof. H. E. Armstrong, 166
Alkali: Industry, The, Prof. J. R. Partington. Second edition, 688; Metals: Colour of the, Prof. Przibram, 671; The Line Absorption Spectra of the, A. L. M. Sowerby and S. B. Barratt, 180; Perchlorates, The, and a New Principle concerning the Measurement of Space-lattice Cells, Dr. A. E. H. Tutton, 841
Alkaloid Derivatives with attenuated Toxic Power, A series of, M. and M. Polonovski, 35
Alnus viridis, Resin Excretion in the Buds of, F. Dormann, 837
Alps, The Origin of the, Prof. L. W. Collet, 173
Aluminium: Alloys, Deterioration of, Prof. E. Wilson, 211; Crystal Structure of, The Effect of Rolling on the, Dr. E. A. Owen and G. D. Preston, 106; Crystals of, The Distortion of, under Compression. Part I. Prof. G. I. Taylor and W. S. Farran, 841; The Thermal and Electrical Conductivities of, The Effects of Torsion upon, with special reference to single crystals, J. E. Calthrop, 503
Amani Institute, The, 166
Amazon Basin, The Vegetation of the, Prof. R. R. Gates, 34
Amber Routes, Prehistoric, in Europe, J. M. de Navarro, 172
Amenhetep Temple at Beisan, The, 353
America: Botanical Society of, Dr. L. H. Bailey elected president of the, 286; The Spider Crabs of, Miss Mary J. Rathbun, 177; Western, Climate Changes in, 238
American: Association: Dr. L. H. Bailey elected president of the, 286; Prize awarded to Prof. D. C. Miller, 61; The Kansas City Meeting of the, F. Thone, 286; Bison: The, a questionable experiment, Dr. J. Ritchie, 275; Carnivores, Extinct, C. Frick, 768; Chemical Society: New York Section, award of the Nichols medal to Dr. S. C. Lind, 281; Prof. B. Brauner elected an honorary member of the, 808; Coal Commission, The, Prof. H. Louis, 10; Geographical Society, award of medals of the, 60; Geology, Trends in, Dr. W. C. Mendenhall, 489; Geographical Union: Meeting of the, 765; Transactions of the Sixth Annual Meeting, 495; Indians, The Origin of the, Dr. A. Hrdlička, 172; Medical Association, award of the gold medal of the, to Dr. A. Castellani, 765; Museum of Natural History, election as honorary members of the, of Capt. J. B. L. Noel and Kunwar Dillipat Shah Rai Bahadur, 600; Official Publications, Dr. P. E. Spielmann, 519; Petroleum Institute, gift to the, by the Universal Oil Products Company, 170; Slipper-limpet (*Crepidula fornicata*) an Oyster Pest? Is the, Dr. J. H. Orton, 304
Américanistes, Paris Société des, Prof. K. von den Steinen and Baron E. Nordenskiöld elected honorary members of the, 317
Amino-Acids, The Hydrolytic Properties of certain, L. P. Bosman, 70
Ammonia: Synthesis, The present State of, utilising Coke-oven Gas, G. Claude, 678; The Oxidation of, Prof. J. R. Partington, 590, 756
Ammonites from the Upper Kimmeridge Clay, Dr. E. Neaverson, 321
Ammonium Radical, The, W. H. Mills and E. H. Warren, 65
Amniotic Pressure, Abnormalities produced by, and their relation to Heredity, J. T. Cunningham, 417
Amphipoda, Fresh-water, H. Spandl, 837
Anacyclus Pyrethrum, Mitosis in, Miss Joyce F. Raves, 914
Anaerobic Respiration, The Crystalline Style and, C. Berkeley, 518

Anatomy: The Evolution of, a Short History of Anatomical and Physiological Discovery to Harvey, Dr. C. Singer, 188

Ancient Wooden Structure at Ipswich, An, J. Reid Moir, 45

Andaman Sea Basin, The, Major R. B. S. Sewell, 64

Anglo-Saxon Cemetery at Girton College, Cambridge: The, a Report based on the MS. Notes of the Excavations made by the late F. J. H. Jenkinson, E. J. Hollingworth, and M. M. O'Reilly, 619

Angola et Rhodesia (1912–14), Mission Rohan-Chabot sous les auspices du Ministère de l'Instruction publique et de la Société de Géographie. Tome 4: Histoire naturelle. Fasc. I.: Mammifères, 114

Animal Breeding, The Physiology of, with special reference to the Problem of Fertility, Dr. F. H. A. Marshall and J. Hammond, 717

Animals: Experiments in the care of, 630; the Royal Society for the Prevention of Cruelty to, Address on the Work of, Capt. F. MacCunn, 278; the Welfare of, A London University Society to promote interest in, Capt. C. W. Hume, secretary, 278

Anion, Hydrogen as, Prof. G. N. Lewis, 824

Anorganischen Chemie, Handbuch der Arbeitsmethoden in der, Gegrundet von A. Stahler. Fortgefuhrt von Prof. E. Tiede und F. Richter. Zweiter Band. Zweite Halfte. Vierter Band Zweite Halfte, 750

Anthracopupa britannica sp. nov., a land Gastropod from the Keele Beds of Northern Worcestershire, L. R. Cox, 707

Anthrax Infection, Some Experiments on, G. Blanc and J. Caminopteros, 810

Antimonial Analogues of the Cacodyl Series, Prof. G. T. Morgan and G. R. Davies, 252

Anti-Tetanic Serum, Estimation of, Prof. P. Bardelli, 671

Antithamnion, The *bromuques* of, C. Sauvageau, 218

Antithamnionella sarniensis, The Localisation of Bromine in, C. Sauvageau, 35

Apes and Men, The Brains of, Prof. G. Elliot Smith, 573

Aphrodite aculeata, Mahalah G. C. Fordham, 375

Apple Scab, Some Relations of Environment to the Epidemiology and Control of, G. W. Keitt, 575

Apples in Cold Storage, Functional Diseases of, Drs. F. Kidd and C. West, 172

Aptitude and Achievement, Prof. J. McKeen Cattell, 87

Archimedes, The Loculus of, R. D. Oldham, 337

Archiv der Julius Klaus-Stiftung, Heft 3 and 4, 765

Arctic: Expeditions, New, 696; Ice in 1925, 568

Argon: in the Blood, The, L. Hackspill, A. P. Rollet and M. Nicloux, 610; The fine Structure of the X-ray Absorption Edge in the *K*-series of, and its possible Interpretation, Dr. D. Coster and J. H. van der Kuuk, 586

Army, Report of the Health of the, 1923, 462

Arsenic Trioxide, Vapour Pressures of, E. R. Rushton and F. Daniels, 465

Arthaśāstra, Chemistry in the, Prof. E. O. von Lippmann, 100

Arthrodira, Zoological Position of the, Dr. E. Stensio, 28

Arthropoda, Trial and Error in the behaviour of certain, Prof. W. E. Agar, 99

Artificial Horizon in Photographic Measurements of Buildings or other Structures, Use of an, A. Mallock, 338, T. F. Connolly, 519

Ascidia mentula, A Molecular Concentration of the Internal Medium of, M. Duval and M. Prenant, 255

Asclepias, Flagellates in the latex of, F. O. Holmes, 907

L'Asie, La tectonique de, E. Argand, 863

Asiatic Society of Bengal, award of the Barclay memorial medal for 1925 to Lt.-Col. J. Stephenson, 355

Astronomic Determinations by U.S. Coast and Geodetic Survey and other Organisations, Sarah Beall, 140

Astronomical Physics, F. J. M. Stratton, 445

ASTRONOMICAL NOTES

Comets:
  Comet Ensor, 63; New Comet, 171; Comets, 282, 356, Ensor's Comet, 393, 428; Comets, 496, Ensor's Comet, S. Seliwanow, and others, 566; Comets, 766, 802

Instruments:
  The New Greenwich Sidereal Clock, W. Bowyer, 98; The Johannesburg 24-inch Refractor, 463; The Spectrohelioscope, Dr. G. E. Hale, 802

Meteors:
  The December Meteors, W. F. Denning, 63, The January Meteoric Shower, W. F. Denning, 98; Two Fireballs, W. F. Denning, 496; Fireball on April 9, W. F. Denning, 633; Fireball on May 2, W. F. Denning, 766

Observatories:
  The Hamburg Observatory, Bergedorf, 601

Planets:
  The Brightness of Saturn's Ring, B. Fessenkoff, 134; Prof. W. H. Pickering's Work on Mars, 171, The Temperatures of the Planets, Dr. E. Schoenberg, 319; Neptune's Satellite, Prof. Eichelberger, 428; Penumbral Lunar Eclipses, G. Blum, 463; Investigations of Transits of Mercury, Dr. R. T. A. Innes, 668; The Rotation of Venus, H. McEwen, 734, Minor Planets, B. Asplind, 802; Neptune's Satellite, Prof. Eichelberger and A. Newton, 906, Temperature of Mars, W. W. Coblentz, 906

Stars:
  Star Fission and Cepheid Variability, Dr. J. H. Jeans, 98; The New Cosmogony, Dr. J. H. Jeans, 134; Automatic Registration of Star Transits, B. Strömgren, 171; Photographic Stellar Photometry, J. A. Parkhurst and Miss Farnsworth, 208; The Measurement of Stellar Radiation, Dr. G. E. Hale, 393; Nova Pictoris, Prof. J. Hartmann, 393; The Distribution of Non-Galactic Nebulæ, F. H. Seares, 428; A Remote Stellar System, Hubble, 496; The Distribution of O-Stars, B. Gerasimovic, 527; Masses of Stars of Types F to K, B. P. Gerasimovic, 668; Nova in a Spiral Nebula, 700; The Nova in Messier 61, 766; Wolf's Nova of October 1925, Dr. W. H. Steavenson, 836; Colour Studies of Variable Stars, J. Hopmann, 836; Parallax Survey of Kapteyn's Selected Areas, O. J. Lee, 836

Sun:
  Sunspot Data from China, Father Chevalier, 27; The Physical Nature of the Solar Corona, Dr. W. Anderson, 27; Naked-eye Sunspots, 63; The Total Eclipse of the Sun, January 14, 98; Recent Sunspots, 171; Measurements of Radiation in the Solar Corona, E. Pettit and S. B. Nicholson, 171; Recent Sunspot and Magnetic "Storm," 208; Recent Sunspot Activity, 282; A Homeric Eclipse, Dr. C. Schoch, 282; Recent Sunspots, 319; A Large Sunspot, 356; Recurrence of Magnetic "Storm," 356; The Temperature of Sunspots, Prof. V. Bjerknes, 463; The Eclipse of Odysseus, Dr. C. Schoch, 496; The Distribution of Radiant Energy over the Sun's Disc, W. J. H. Moll, H. C. Burger, and J. van der Bilt, 527; Brilliant Solar Outburst, J. Evershed, 566; Measures of the Sun's Diameter, G. Armellini, 566; Relativity Shift of Solar Spectrum Lines, Dr. C. E. St. John, 633, Naked-eye Sunspot, 700; The Sun's Velocity derived from Faint Stars, P. van de Kamp, 700; Sun's Rotation Period as determined from Auroræ, G. J. Burns, 734; Motion of Sunspots in Latitude, R. Sekiguti, 734; Recent Solar Activity, 906

Miscellaneous:
  The Spectrum of the Recent Aurora, Prof. L. Vegard, and others, 356, Recent Magnetic Disturbance, 393; Auroral Display of March 9, 428; Magnetic "Storm," Aurora, and Solar Disturbance, 601

Astronomy: Popular, 819; The next Task of, Prof. R. A. Sampson, 725

Astrophysics, Application of Subatomic Thermodynamics to, Prof. W. N. Saha, 672

Athenæum: Club, elections to the, 207; History of the, 1824–1925, H. Ward, 814

Atlantic Doldrums, C. S. Durst, 703

Atmosphere, The, and Human Comfort, Dr. C. F. Brooks, 528

Atmospheres, neutral, An Apparatus for continuous Percolation and for Filtration in, B. S. Evans, 470

Atmospheric: Diffusion shown on a Distance-neighbour Graph, L. F. Richardson, 180; Ozone and Terrestrial Magnetism, Dr. C. Chree, 251; Physics, Some recent Advances in, Prof. S. Chapman, 537; Pollution, Committee for the Investigation of, Report of the, 241
Atmospherics, On the Nature of (II.), Dr. E. V. Appleton, R. A. Watson Watt, and J. F. Herd, 841
Atom, The Law of Force within the, Dr. H. Pettersson, 530
Atomic: Number 61: the Element of, Discovery of, Dr. B. S. Hopkins, and others, 391; Illinium, The Element of, J. A. Harris, L. F. Yntema, and Prof. B. S. Hopkins, 792; Numbers 75, 85, 87, and 93, Foreshadowing, by means of X-rays, F. H. Loring; Adam Hilger, Ltd., 153; The Writer of the Note, 154; Structure, Chemistry and, Dr. J. D. Main Smith, 373; Weights, The Constancy of, Prof. H. V. A. Briscoe and P. L. Robinson, 377
Atomistic Physics, Prof. A. Sommerfeld, 388
Atoms: in Solid Bodies, The Exchange of, in Consequence of Heat-movements, G. Hevesy, 775; Radiation and the Disintegration and Aggregation of, Prof. G. E. M. Jauncey and A. L. Hughes, 743
Aurora: Borealis and Magnetic Perturbation of March 9, 1926, The, at the Meudon Observatory, H. Deslandres, 610; Recent, The Spectrum of the, Prof. L. Vegard, 356; The Spectrum of the, Prof. J. C. McLennan, 867
Auroræ in Southern Norway, Photograms of, Prof. C. Størmer, 855
Auroral Display of March 9, 428
Australasia, The United States and anthropological work in, 240
Australia: an Expedition to the Northern Territory of, 764; Prickly-pear in, The Campaign against, A. P. Dodd, 625; problems presented by primary and secondary industries, Sir Frank Heath inquiring into, 460; scheme for the re-organisation of the Commonwealth Institute of Science and Industry, Sir Frank Heath, 697; the Commonwealth of, Salient Features in the Stratigraphy, Tectonic Structure, and Physiography of, Sir T. W. Edgeworth David, 607; The Flora of, xxxi., Prof. A. J. Ewart and A. H. N., Petrie, 367; the Institute of Science and Industry, appointment of an executive committee for, 764; visits of representative overseas lecturers to, 597
Australian: Aborigines, Teeth and Jaws of the, Dr. T. D. Campbell, 837; Coccidæ, with descriptions of new species, W. W. Froggatt, 36; Diptera, Notes on, No. VIII., J. R. Malloch, 811; Encyclopædia, The Illustrated. Edited by A. W. Jose and H. J. Carter. Vol. I., 649; Essential Oils, The germicidal values of some, and their pure constituents, together with those of some essential oils, A. R. Penfold and R. Grant, 142; Fossil Jelly-fish, An, F. Chapman, 344; Fossil Plants referable to the genus Leptophlœum, Dawson, On some, J. Walton, 810; Sponge-crabs, The Development of two, H. M. Hale, 106; Syrphidæ in the Bishop Museum (Diptera), The, C. H. Curran and E. H. Bryan, jun., 811; Termites (Isoptera), G. F. Hill, 366; Volcanic Rocks, The Magnetisation of, P. L. Mercanton, 915; Wind Storms, S. S. Visher and D. Hodge, 284
Australol, The Constitution of, J. C. Earl and V. M. Trikojus, 71
Autoxidation and Antioxygen Action, C. Moureu and C. Dufraisse, 774
Avian Migration, 712
Aviators, an Italian *Annuario* for the use of, 734
Avicenna's "Mineralia," The Arabic Text of, E. J. Holmyard, 305
Avogadro's Constant, Determination of, by means of Doubly Refracting Solutions of Dialysed Iron, L. Tieri, 71
Ayrton, Hertha, 1854–1923: a Memoir, Evelyn Sharp, 782

Bacillus Radicicola (Beij.), The Life-cycle of, in Soil, and its Relation to the Infection of the Host Plant, H. G. Thornton and N. Gangulee, 289
Bacterial Growth, Effects of Polarised Light on, Prof. S. S. Bhatnagar and R. B. Lal, 302
Bacteriology: Prof. C. H. Browning, 79; a Text-book on Fundamentals, Prof. S. Thomas, 11; and Immunity, General and Pathogenic, Laboratory Manual in, Prof. V. A. Moore and Prof. W. A. Hagan, 11
B. ægypticus, Studies on. Part I, Mohammed Ali, 537
Badger, The Life Story of a, J. C. Tregarthen, 371
Bailey: Loring Woart, The Story of a Man of Science, J. W. Bailey, 886
Bakerian Lecture, Prof. A. S. Eddington, 770
Baltic, Hydrographical Conditions in the, 907
Balwantia Soleniformis (Benson), Distribution and Habits of, S. L. Hora, 678
Banana: in America: Origin of the, Dr. E. W. Berry, 209; The, Prof. R. H. Lowie, 517; The Original Home of the, Dr. A. W. Hill, 757
Band Lines, Alternating Intensities in, Dr. J. C. Slater, 555
Barley, the Coleoptile of, Effect of Minute Electric Currents on the Growth Rate of, F. G. Gregory and L. Batten, 217
Barlow's Tables, J. Wishart, 856
Bath Springs, The, Dr. R. H. Rastall, 908
β-dinaphthylene Oxide, The Nitric Compounds of, Prof. H. Ryan, D. T. Flood, and P. T. McNulty, 364
Beaufort, Admiral Sir Francis, and the Beaufort Scales of Wind and Weather, L. G. Garbett, 437
Beauty, The Evolution of, C. H. Henshaw, 893
Beisan, Palestine, Excavations at, A. Rowe, 526
Belgium, Royal Academy of Sciences, Letters and Arts (Scientific Class) of, Prof. A. Brachet elected a member and Prof. C. Pérez a foreign associate of the, 868
Ben Lawers and Meall Corranaich (Perthshire), The Geological Structure of, Gertrude Lilian Elles, 470
Bengal, Race-mixture in, Analysis of, P. C. Mahalanobis, 402
Bentonite, The Minerals of, C. S. Ross and E. V. Shannon, 768
Benzene Molecule, The Electronic Structure of the, L. Pauling, 908
Benzole Research, 769
Bernoulli's Numerical Solution of Algebraic Equations, A. C. Aitken, 878
Beryl, $Be_3Al_2Si_6O_{18}$, The Structure of, Prof. W. L. Bragg and J. West, 913
Bessemer gold medal of the Iron and Steel Institute, awarded to Sir Hugh Bell, 565
Bhadra Yāna, Haraprasad Shastri, 402
Binary System: The Effect of Varying Mass on a, a correction, Prof. E. W. Brown, 402
Biochemical Society, Dinner of the, 424
Biochemistry, Clinical, Dr. I. Maxwell, 372
Biological Problems, 260
Biologie, Ergebnisse der, Herausgegeben von K. v. Frisch, and others, Erster Band, 783
Biologischen Arbeitsmethoden Handbuch der, Herausgegeben von Prof. E. Abderhalden: Lief. 173, Abt. 9: Teil 2, 1 Hälfte, Heft 2, 513; Lief. 182, Abt. 9: Teil 1, 2 Hälfte, Heft 1, 785
Biology: and Human Life, 779; and Social Hygiene, Prof. J. A. Thomson, 243; Experimental, Society for, Spring Meeting of the, 633; International, Prof. V. Kellogg, 806; Quantitative, 410; *Quarterly Review of*, No. 1, 492; The Growth of, Zoology from Aristotle to Cuvier, Botany from Theophrastus to Hofmeister, Physiology from Harvey to Claude Bernard, the late Dr. W. A. Locy, 779
Biot, A Tribute to the Memory of (1774–1862): Optical Rotatory Dispersion, Prof. T. M. Lowry, 271
Bird: Life and Natural Selection, 851; Migration, Problems of, Dr. A. L. Thomson, 712
Birds: British: A. Thorburn. New edition. In 4 vols. Vol. 2, 447; The Pocket-book of, R. Kearton and H. Bentham, 585; In Praise of, Pictures of Bird Life, Described and Photographed by the Rev. Canon C. F. Raven, 227; of Eastern China, A Handbook of the, J. D. D. La Touche 2 parts, 650; of the Riviera: The, Being an Account of the Avifauna of the Côte d'Azur from the Esteral Mountains to the Italian Frontier, C. Ingram, 785; The Courtship of, Prof. J. S. Huxley and others, 571; The Origin of, G. Heilmann; Dr. H. Gadow, 883
Birmingham University: appointments; the title of emeritus professor to be conferred on Sir John

Cadman, gifts to, 250, Report of, 362; appointment, gifts to, 399; appointments, 534, gifts to, 840, the Department of Oil Engineering and Refining, 912
Birth Control: Dr L Dublin, 26, Clinics, Society for the Provision of Annual Report of the, 133
Birthdays, Contemporary, 33, 69, 105, 141, 178, 216, 251, 289, 324, 363, 400, 436, 469, 502, 536, 572, 609, 641, 677, 707, 741, 773, 808, 841, 877, 913
Biscayan Plankton collected during a Cruise of H M S. *Research*, 1900. Pt. XIV., G. P Farran, 609
Bishop, Bernice P, Museum, Sea Expeditions of the, 732
Bison: The American, a Questionable Experiment, Dr. J. Ritchie, 275
Black: Body: Radiation Isotherm, Thermodynamic Derivation of a, B Bruzs, 811; Spectrum, Law of Distribution of the Energy in the, Gianfranceschi, 843, '-coated' Professions, The Increase in the Numbers entering the, and the Lack of Skilled Manual Workers, 433, Cypress Pine, The (*Callitris calcarata*, R. Br), Tannins and their Distribution in the Bark, F. A. Coombs, W McGlynn, and M B. Welch, 142; Ven and Stonebarrow, The Black Marl of, in the Lias of the Dorset Coast, W. D Lang, L. F Spath, and others, 70
Blacks and Pitches, H M Langton, 584
Blood: and Shock, The Relationship between Viscosity of the, Dr R A. Waud, 487, Characteristics and Race, 602, Glycolysis in, A. D. Stammers, 743; On the Presence of α-Hydroxy-acids in, A. D Stammers, 743, The Germicidal Action of the, Effect of Ultra-violet Rays on, Colebrook, Hill, and Eidinow, 357
Body during Sleep, The Significance of Changes in the Electrical Resistance of the, C P. Richter, 743
Bæckea Gunniana var *latifolia* (F. v M), The Essential Oil of, A R Penfold, 142
Boiler-house, The Modern, Eng.-Capt. E. C Smith, 488
Borneo, Explorations in, Dr. E. Mjoberg, 249
Boron in Aluminium and Aluminium Alloys, P Hænni, 35
Boskop Skull, The: W P. Pycraft, 196; Dr. R Broom, 589
Bosnia, An Arctic Fish in, Dr St J Bolkay, 135
Botanical Society of America, election of corresponding members of the, 318
Botany of Bihar and Orissa, The, an Account of all the known Indigenous Plants of the Province and of the most Important or most commonly Cultivated Exotic Ones, H H. Haines 5 Parts, 225
Botrylloides, The Development of, and its Bearing on the Ancestry of the Chordata, Sylvia Garstang and Prof W Garstang, 365
Boulogne-sur-Seine, The Explosion at, G. Claude, 401
Boxer Indemnity, the Utilisation of the, Appointment of three Chinese members of the Committee on, 278
Boyle, Robert, Lecture, Prof J Joly, 592
Branchiopod, A Fossil, D J Scourfield, 498
β-rays: from Radium, On the Effects of, upon Division and Growth of Cancer Cells, Prof J. C Mottram, G. M. Scott, and Prof S Russ, 678, The Absorption of the, by Matter, Mme J S Lattès and G. Fournier, 35
Brighter Biochemistry, No 3, 207
Brightness, Intrinsic, A P. Trotter, 305
Bristol Museum and Art Gallery, Annual Report of the, 317
British: Avifauna, Two Additions to the, Admiral J. H Stenhouse, 383; and Danish Farming, The Productivity of, R J. Thompson, 325; Aphides, A List of (including Notes on their Synonymy, their recorded Distribution and Food Plants in Britain, and a Food-Plants Index), Dr. J Davidson, 512; Association: at Oxford. Preliminary Programme, 491, Sectional Presidents of the, 95, Sir Arthur Keith to be nominated president of the Leeds meeting, 427, Birds, A Thorburn New edition In 4 vols Vol 2, 447, Carboniferous Murchisoniidæ, A Revision of the, with Notes on their Distribution, and Descriptions of some New Species, Jane Longstaff (*née* Donald), 843, Dyestuffs Corporation, Ltd, Developments of the, 352, East Africa, A Live Game-collecting Expedition to, 564, Electrical and Allied Industries Research Association, Report of the, 279; Freshwater Pearl Mussel, The. Part 2, J W. Jackson, 173; Honduras, Expedition to, T. A Joyce, 241; Journal Photographic Almanac and Photographer's Daily Companion, 1926, edited by G E Brown, 299; Mammals: More Chats on, Rodents and Rats, Dr J J Simpson, 371; Marine Biology, Prof. J S. Gardiner, 30, Medical Association. award of the gold medal of the, to Sir Humphry Rolleston, 905, Major J Hall-Edwards elected an honorary member of the, 600; Museum: request by the Trustees for further help, 318; (Natural History). picture postcards of the, 317, 565; Sir Henry Miers elected a trustee of the, 494, Non-ferrous Metals Research Association, Report of the, 799; Optical Science, 505; Post-pliocene Unionidæ, A. S Kennard, A E Salisbury, and B B Woodward, 321, Science: and Invention, Ll. B. Atkinson, 369; Guild, Annual Meeting of the, 675, 681; News Service, A, 329, Universities, 581, West Africa, Impressions of, Hon. W Ormsby-Gore, 800
Broadcasting: and the Electrical Industry, Capt P. P. Eckersley, 676; Committee, Report of the, 390; in Great Britain, 473
Bronn's, Dr. H. G. Klassen und Ordnungen des Tierreichs wissenschaftlich dargestellt in Wort und Bild. Sechster Band, Abt 1: Lief. 39, Funfter Band, Abt. 2; Lief. 100; Dritter Band, Buch 2, Lief 147, 511
Brooks Research Fund in Johns Hopkins University, establishment of a, 535
Brown Algæ of the Arctic Region exposed at Low Tide, The Gaseous Exchanges of the, T Krascheninnikoff, 708
Bruce Memorial Prize, award of the, to J M. Wordie, 800
Bubbles in Water, Some Phenomena occurring at the Surface of, T. Alty, 180
Buddermokan, Sir Richard Temple, 429
Bunt, Treatment of Grain for, K. Sampson and D. W Davies, 430

Cable Industry, Science in the, P Dunsheath, 698
Cadmium and Nickel Hydroxides, Crystalline Structure of, G. Natta, 367
Calcium: Barium, and Strontium Oxides, Melting Points of, E. E Schumacher, 498; Sulphate, Solubility of, R. E Hall, J A. Robb, and C E. Colman, 768
Calculus of Variations, A Chapter in the, Prof. A. R Forsyth, 70
Californian: Anthropometry, E W Gifford, 767 Archæology, E. W Gifford and E. E Schenck, 906
Cambrian Slate-belt of Nantlle (Carnarvonshire), The Stratigraphy and Structure of the, T O. Morris and W G. Fearnsides, 326
Cambridge University: appointments in, candidates for entrance scholarships and exhibitions, 32, R E Priestley appointed assistant registrary; successful candidates in the scholarship examinations, 68, appointments; award of a Gordon Wigan prize to F. H Constable, 177; plans for the departments of Pathology and Animal Pathology, 215; amendments to the general regulations for prizes and medals, 250; appointments in, 288, the department of Pathology, 323; elections, regulations governing medical studies; proposed publication of summaries of research degree theses, 362; appointment and election, 399, local lectures, 399, appointments; award of Rayleigh prizes to R C. Cooper and H Horrocks, and of Smith's prizes to G S Mahanjani and Ll H Thomas, Report of the University Appointments Board, 435, award of the Allen scholarship to R Cooper; offer by Sir Alfred and Lady Yarrow of a lectureship in Assyriology, Dr. D Stockdale elected a fellow of King's College, 468; regulations of the new statutes, Report of the Board of Research Studies, 640, proposed change in the scheme of studies for the ordinary B.A degree; the status of lecturers and tutors giving instruction

in the country, 676; bequest to, by Sir John B. Harrison; appointments; the readership in ethnology, 706; the General Strike and, 740; interim report on lectureships and demonstratorships; J. Gray appointed University lecturer in experimental zoology, 772; proposed graces for the conferment of honorary degrees, 807; approval of the statutes of the Commissioners; offer of the University Automobile Club; Report of the Committee for Geodesy and Geodynamics; return of astronomical instruments from the Crimea, 876; bequest by W. W. Rouse Ball, 912; bequest by Dr. J. E. Bles, 840
Cameroon Mountain, Renewed Activity of, Dr. J. D. Falconer, 518
Campanula Mutants, Miss A. E. Gairdner, 837
Camphor: The Rotatory Dispersion of, L. Longchambon, 610; The Rotatory Power of, R. Lucas, 401, 810
Canada: Helium in, Prof. J. C. McLennan, 93; Triangulation in, 600
Canadian: Expedition of 1922 to the Arctic Archipelago, The, J. D. Craig and Major R. A. Logan, 25; Salmon, Menzies, 429
Cancer: Biology of, 335; Inquiry, The League of Nations, 571
Cane-sugar, Inversion of, S. W. Pennycuick, 431
Canet, Gustave, Memorial Lecture, The, Air Vice-Marshal Sir W. Sefton Brancker, 698
Cannizzaro Memorial Lecture, The, Sir William Tilden, 840
Cape to Cairo Kinematograph Film, Major C. Court Treatt, 525
Capillarity, The Application of Radiography to the Study of, E. A. Owen and A. F. Dufton, 470
Capillary Chemistry, Some Phenomena of, R. Dubrisay, 253
Capsian Affinities of the later Stone Age Culture of South Africa, A J. H. Goodwin, 669
Carbohydrate/Nitrogen Relation in Horticulture, H. W. Hooker, 173
Carbon: and Silicon: the two Foundation Stones of the World, Prof. H E. Armstrong, 683; Dioxide: Leakage of, from Ships' Holds, A. J. Smith, 604; The Decomposition of, under Reduced Pressure: by the Condensed Spark, P. Jolibois, H. Lefebvre, and P. Montagne, 810; by the Electric Spark, Influence of the Capacity of the Discharge Circuit on, P. Jolibois, H Lefebvre, and P. Montagne, 879, Disulphide and Liquid Air, fatal accident by an explosion of a mixture of, 97; Monoxide: and Oxygen Mixtures, The Combustion of Well-dried, Parts I. and II., Prof. W. A. Bone, F. R. Weston, R P. Fraser, and D M. Newitt, 324; Molecule: the Neutral, The Spectra of, Dr R. C. Johnson, 376; The Energy Levels of the, Prof. R T Birge, 229, Spectrum, The Structure of the Bands 4511 and 4123 of the, Mlle. O. Jasse, 610; Tetrachloride, The Photographic Measurement of the Electrostriction in the Case of, Pauthenier, 290
Carbonate and Nitrate Crystals of the Calcite Type, On the Electrostatic Potential Energy and the Rhombohedral Angle of, Prof. S. Chapman, J. Topping, and J. Morrall, 469
Carbonic Acid, The Stability of Solutions of, A. Kling and A. Lassieur, 290
Carboniferous Limestone (Avonian), The, Succession of a Portion of the North Crop of the South Wales Coalfield, T. N. George, 843
Carbonyl Radical, The Magnetic Properties of the, P. Pascal, 327
Carlsruhe Technische Hochschule, the Chemical Institute, Prof. A. Stock appointed director of, 808
Carnegie: Endowment for International Peace, Report on the Division of Intercourse and Education, 808; Institution of Washington, Department of Terrestrial Magnetism, Report for 1925, 667; Trust for the Universities of Scotland, The, 360; United Kingdom Trust, Twelfth Annual Report, 763
Carnot's: Cycle and Efficiency of Heat Engines, S. S. Cook; R. Dowson, 266; Tract, address at the centenary celebration of the publication of, D. Berthelot, 494
Catalytic Action: of Metals of the Platinum Group and their Degree of Subdivision, The. I., G. R. Levi and R. Heardt, 539; Passivity, and other Phenomena, Dr. A. S. Russell, 47
Catechol, The Crystal Structure of, W. A. Caspari, 805
Cathode: Ray Oscillator, The, F. R. Terroux, 137; Rays, Secondary, The Velocity of, Dr. A. Becker, 100
Cave-Animals, Blindness of, J. T. Cunningham, 50
Cayman Islands, B W.I., Geology of the, and their Relation to the Bartlett Trough, C. A Matley, with appendix by T. W. Vaughan, 707
Caytoniales and Modern Flowering Plants, The Relation between the, Dr. H. H. Thomas, 290
Cell Interior, Further Micro-injection Studies on the Oxidation-reduction Potential of the, J. Needham and Dorothy Needham, 289
Cells, Artificial, 284
Cellulose Ester Varnishes, F. Sproxton, 785
Central: America, the plants of, Dr. P. C Standley, 733; Australia, Cretaceous Glaciation in, W G. Woolnough and Sir T. W. Edgeworth David, 573
Cereals, The Genetics of, Dr. K. V. Stolze, 360
Cerebellar Cortex, The Action of Strychnine on the, Prof. F. R. Miller, 486
Ceva's Theorem, An Extension of, to Polygons of any Number of Sides, A. Brown, 70
Ceylon: Bibliography of Books and Papers relating to Agriculture and Botany to the end of 1915, T. Petch, 733; The Stone Age of, Dr. F Sarasin, 567; The Stone Age in, Dr. H. O. Forbes, 589
Charcoal Surfaces, Oxidation at, Miss M. Wright, 401
Charlottenburg: Technische Hochschule, Dr. W. Eitel nominated professor of Mineralogy at the, 876; University, establishment of a lectureship in 'Technical English,' 773
Chatham Islands, The Fauna of the, E. Meyrick and others, 739
Chemical: Analysis: Errors of Judgment in, Dr J F. Tocher, 641; Qualitative, Outlines of, Prof. F. A. Gooch and Prof. P. E Browning. Fifth edition, 549; and Physical Action at Surfaces, Dr. E K. Rideal, 626, Congress, The Italian, at Palermo and the Cannizzaro Centenary, 840; papers, aim at uniformity in referring to original, 425; Society: resignation of Dr. A. W. Crossley as president; nomination of Prof H B. Baker as president, 207; and taxation, 866; Publications Fund, Prof. J. Thorpe, 487; Synonyms and Trade Names: a Dictionary and Commercial Handbook, W. Gardner. Second edition, 618
Chemistry: and Atomic Structure, Dr J. D. Main Smith, 373, Colloid, Laboratory Manual of Elementary, E. Hatschek. Second edition, 447; Crystals and, 508; Inorganic: a Text-Book of, edited by Dr. J. Newton Friend. Vol. 3, Part I.: The Alkaline Earth Metals, Dr. May Sybil Burr (née Leslie), 853; and Theoretical, A Comprehensive Treatise on, Dr. J. W. Mellor. Vol. 6, 683; Institute of, address to the, Prof. G. G. Henderson, presentation of the Mendola medal to Dr. H. Phillips, 354; in the Arthasastra, Prof. E. O. von Lippmann, 100; Laundry, a Short Handbook on the Chemistry of Laundry Materials and Methods, A. Harvey, 889; Organic. An Introduction to, Prof. A. Lowy and Dr. B. Harrow, 412; Introduction to the Study of, a Theoretical and Practical Text-book for Students in the Universities and Technical Schools, Dr. J. Wade, revised by Dr. H. Stephen. New and enlarged edition, 752; Physical: A Summary of, Prof. K Arndt, translated by W. H. Patterson, 412; A System of, Prof. W. C. McC. Lewis. In 3 vols. Vol. 2: Thermodynamics. Fourth edition, 447; in Biology and Medicine, Prof J. F. McClendon and Prof Grace Medes, 410, Physiological, An Intermediate Text-Book of, with Experiments, Prof. C J. V Pettibone. Third edition, 372; Practical Physical and Colloid, for Students of Medicine and Biology, Prof. L Michaelis, translated by T. R. Parsons, 335, The Inspiration of, Prof. A. Smithells, 40, Three Centuries of, Phases in the Growth of a Science, Prof. I. Masson, 40; to the Time of Dalton,

E. J. Holmyard, 336; Vegetable, Contributions to Comparative. XII.: Chemistry of Barks, J. Zellner and colleagues, 611
Chichen Itza, Yucatan, Archæological Investigations at, Dr. S. G. Morley, 497
Chimica: e dell' alchimia in Italia, Sulle fonti storiche della, Dr. G. Carbonelli, 544; Generale ed applicata all' industria, Trattato di, Prof. E Molinari. Vol. I.: Chimica inorganica. Parte Seconda. Quinta edizione, 585
Chimique des bois: L'industrie, leurs dérivés et extraits industriels, P. Dumesny et J. Noyer. Première et Deux Partie. Deux. édition, 717
China: Eastern, A Handbook of the Birds of, J. D. D. La Touche. 2 parts, 650; Educational Progress in, H. Balme, 564; Geological Survey of, Progress of the, 426; Modern, The Spirit of, 480
Chinese Point of View, The, F Anson, 278
Chips from a Sculptor's Studio, J Tweed, 460
Chirocephalus diaphanus, The Post-embryonic Development of, H. G. Cannon, 573
Chlorocruorin: a Pigment allied to Hæmoglobin, H. M. Fox, 217
Chlorine, the Isotopes of, Separation of, Prof W. D. Harkins and F. A Jenkins, 285
Chloropicrin, The Antiseptic Power of, H Violle, 366
Chromic Chloride Hexahydrates, The Isomeric, Prof. J. R. Partington and S. K. Tweedy, 415
Chromium, Allotropy of, A. J. Bradley and E. F Ollard, 122
Chrysoberyl, The Crystalline Structure of, Prof W. L. Bragg and G B Brown, 180
Cirrus: at a Lower Level than Alto-cumulus, C. J. P Cave, 199; Clouds over Melbourne, The Annual Variation in the Velocity of, E. Kidson, 366
Cirsium eriophorum, Dr G. Claridge Druce, 305
Citrus Fruit in the Philippines, A. H. Wells, F. Agcaoili, and Maria Y. Orosa, 320
Civil Engineers, Institution of, awards of the, 830
Cladocera, The Absence of an Innate Sexual Cycle in, Dr A. M. Banta, 804
Clay, The Anomalous Flocculation of, Dr. A F Joseph and H. B. Oakley, 624; W. O Kermack and W. T. H. Williamson, 824
Clifton College Scientific Society, Report for 1924–25, 599
Climate: and Man in the United States, L. C. W. Bonacina, 442; and Plant Distribution, Dr. E. J. Salisbury, 497, Changes in Western America, 238
Climatic Changes and the Wegener Theory, Dr. G. C. Simpson, 172
Coal: Banded Constituents of, The Nomenclature of the, C. A. Seyler, 486; Commission: Found, What the, an Authoritative Digest and Summary of the Facts about Coal, by Staff Members. Edited by E. E. Hunt, F G Tryon, and J H Willits, 10; Report of the, 405; Conservation and the Gas Industry, Prof J. W Cobb, 51, -dust Explosions, Release of Pressure in, Dr. R. V. Wheeler and H. P. Greenwald, 174, Face, The Applications of Machinery at the, S. Mavor, 563; Fire, The, J. D. Fulton, 859; -mining Industry: in Great Britain, The, Prof. H Louis, 405; The Future of the, Sir Richard Redmayne, 675; Plant Cuticles in, V. H. Legg and Prof. R V. Wheeler, 430; Production, Practical, Preliminaries of Coal Mining. Prospecting, Explosives, Development, Drainage, Ventilation, F. H. Kreeland, 784; Products from, 296, Report, The, No Solution, L. Lawton, 598; -tar Products, The Industrial Applications of, H. M Bunbury and A. Davidson, 296; the Chemistry of, Researches on. Pt. IV, Prof. W. A. Bone and R. Quarendon, 251; The Discovery of Concealed, S and J. Bailey, 495; The Microscopic Structure of, Dr. R. Thiessen, 804; Utilisation and Research, Prof. J. W. Cobb, 613
Coalfield, The Yorkshire and Nottinghamshire, 783
Coalfields of Scotland, appointment of a committee on the, 26
Coals of Oriental origin, low temperature carbonisation of, A. Shimomura, 26
Cobija and Lampa Meteoric Stones, The Identity of the, E. D. Mountain, 537
Cobra Venom, The Action of, on Plants, Sir J. C. Bose, 834
Coefficient of Expansion of Substances in the Amorphous State, The Change of the, Michel-Samsœn, 439
Cœur, Le cerveau et le, Prof. G. Fano. Traduit de l'italien par G. Caputo, 43
Colaconema reticulatum, E. Chemin, 775
Coleus, Acidity of the Medium and Root Production in, Miss E. Philip Smith, 339
Colfax Station of the Duquesne Light, The, C W. E. Clarke, 389
Colliery: Management, Prof. Douglas Hay, 687; Working and Management: comprising the Duties of a Colliery Manager, the Superintendence and Arrangement of Labour and Wages, and the Different Systems of Working Coal Seams, H. F. Bulman and Sir R A. S. Redmayne. Fourth edition, 687
Colloids, An Introduction to the Physics and Chemistry of, E. Hatschek. Fifth edition, 412
Colonial Administration, Ethnographical Studies and, 745
Colorado River, La Rue, 804
Colorimeter, A Trichromatic, suitable for Standardisation Work, J. Guild, 326
Colorimetry, J. Guild, 636; A Criticism of the Monochromatic-plus-white Method of, J. Guild, 326; On a New Method of, J. Guild, 326
Colour: Kinematograph Films, L. Eveleigh, 636; -printing of To-day, D. Greenhill, 97; Reaction of the Skin, A, relative to the Genesis of the Melanins, P. Saccardi, 611; Sensitivity of Photographic Materials, Dr. C. E. K. Mees, 904; Vision, Present Problems in, Prof. W. Peddie, 538
Colpidium colpoda, Effects of β-radiation on, as seen in Stained Specimens, J. C. Mottram, 914
Comet: Ensor, 63; New, T E. Blathwayt, 171
Comets, 244, 282, 356, 496, 766, 802
Commonwealth Fund Fellowships, Report on the, 288, 875
Compton Effect, The, M. de Broglie and Dr. A Dauvillier, 321
Condensation Pump, A, working with a Moderate Primary Vacuum, L. Dunoyer, 610
Conferences, Suggestions as to the Procedure at, 599
Congo, A Portrait-statue from the, T. A. Joyce, 64
Congruence of the Second Degree, C. Juel, 775
Conifers, The Pentosan Theory of Cold-resistance applied to, J. Dole and Miss P. Clinch, 642
Contact Rectification by Metallic Germanium, E. Merritt, 182
Continental Drift, Tidal Forces and, F. B. Taylor, 246
Continuous Curves, A Property which characterises, R. L. Wilder, 181
Copper: Arc Spectrum: of, Quartet Terms in the, C. S Beals, 324; The Principal Series of the, Dr. F. Simeon and E. S. Dreblow, 17; Eskimo, Songs of the, D. Jenness and Miss Helen H. Roberts, 870; The Low-temperature Oxidation of, J. S. Dunn, 364, -Tin Alloys, Hardness of, A. Mallock, 787; Tinted Flame Caps, W. Cooper, 35
Coral Reefs, Subsidence of, Prof. W. M. Davis, 736
Corals and Zooxanthellæ, Dr. H Boschma, 245

CORRESPONDENCE.

Abnormalities produced by Amniotic Pressure, and their Relation to Heredity, J. T. Cunningham, 417
Actinium Series, The, and the Lead Ratios in Rocks, Prof. T. R. Wilkins, 719
Adsorption, Theories of, and the Technique of its Measurement, Prof. J. W. McBain, 550

Electrons: Capture of, by α-Particles in Hydrogen, J. C. Jacobsen, 858, Spinning: and the Structure of Spectra, G. E. Uhlenbeck and S. Goudsmit, 264, Prof N Bohr, 265; R de L. Kronig, 550; Dr. J. C. Slater, 587; Prof. A. S. Eddington; Prof O W. Richardson; Prof F. A. Lindemann, 652; Dr J. Frenkel, 653
Elements: of Atomic Numbers 75, 85, 87, and 93, Foreshadowing, by Means of X-rays, F H. Loring, Adam Hilger, Ltd., 153, The Writer of the Note, 154, Transmutation of: a Transmutation of Lead (First Method), Prof. A. Smits, 13, 620; Dr. A. C. Davies and Prof. F. Horton, 152
Entomology, Applied, Dr. P A. Buxton, 623
'Eolith' Factory, An, J. Reid Moir, 723
Ether Drift: Experiment, On Prof. Miller's, Sir Oliver Lodge, 854; Experiments, Prof D. C Miller, 890
Euphausiids, the Metamorphosis of, Numerical Reduction of Instars in, R. Macdonald, 894
Excited Energy, Transfer of, from Ozone to Hydrogen and Nitrogen, Prof A. C. Grubb, 658
Fatty Acids, Higher, X-ray Identification of the, Prof. G. T. Morgan and E. Holmes, 624
Filterable Viruses, Ultramicroscopic Organisms of, Prof. R. R. Gates, 692
Fresh-water Fishes: of New Zealand, Origin of the, W. J. Phillipps, 485; The Distribution of, Sir Herbert Maxwell, 719
Fundamental Frequencies, Three, M. Home, 194
Fungus Rings, Rate of Growth of, J. Ramsbottom, 158
Gammarus chevreuxi, Sexton, New Mutations in, Mrs. E W. Sexton and Miss A. R. Clark, 194
Gaseous Explosions, Infra-red Emission from, Dr W E. Garner, C. H. Johnson, and S. W. Saunders, 790
Genes and Linkage Groups in Genetics, C. Tate Regan, 86, 341, Prof J. S. Huxley, 154, 268; Prof. E. W. MacBride, 232, 340; Prof R. C. Punnett, 514
Genetics, Genes and Linkage Groups in, C. Tate Regan, 86, 341, Prof. J. S. Huxley, 154, 268; Prof. E W MacBride, 232, 340; Prof R. C Punnett, 514
Gentiana campestris var. *alba*, Dr G. Claridge Druce, 270
Geological Congress, The, and Museums, Dr. F A. Bather, 199
Gerlach and Stern's Magnetic Experiments, Intensification of the Metallic Image in, Dr. J. H. J. Poole, 451
Glass, British Chemical, Prof. E. B Poulton, 381
Glauconite, The Constitution of, A F. Hallimond, 453
Greenland or Polar Front, Prof. W. H Hobbs, 232; L. C W Bonacina, 451
Halo, A Very Rare, C. J. P. Cave, 791
Hardness, A Mallock, 117
Heat Engines, Efficiency of, Carnot's Cycle and, S. S. Cook, R Dowson, 266

Heaviside Layer, The Constitution of the, T L. Eckersley, 380
Helium : Excited, Absorption and Resonance Radiation of, W. H. McCurdy, 122 ; D, Line of, On the Structure of the, W. A. MacNair and W. H McCurdy, 159 ; Slow Protons in, The Free Path of, Prof. G. P Thomson, 235
Heredity, the Chromosome Hypothesis of, Spermatogenesis in Spiders and, Prof. E. Warren, 82 ; Prof. J B. Gatenby, 233
Herrings of the Eastern Part of the English Channel, The, W C Hodgson, 342
Heterochromosomes and Polyploidy, Dr. J W Heslop Harrison, 50
Hybridity, Parthenogenesis, and Segregation, A. D. Peacock and Dr. J. W. Heslop Harrison, 378
Hydrogen : as Anion, Prof. G. N Lewis, 824 ; Bigamous, a Protest, Prof. H E. Armstrong, 553 , Doublet, The, Dr W V Houston, 590
Ice-breaking, Use of Thermit in, Prof A S. Eve, 621
Inertia, The Law of, for Radiating Masses, Sir Joseph Larmor, 300
Insect Drift, The Physical Basis of, E. P. Felt, 754
Interference Methods in the Determination of Stellar Diameters, Use of, M Gheury de Bray, 235
Ionisation, Residual, in Closed Vessels, Dr. R. W. Lawson, 235
Iron Atom, The Fundamental Level of the, Prof N. K. Sur, 380 ; O Laporte, 721 , Single Crystals of, Magnetic Properties of, W. L. Webster, 859
Isotopes, The Line Spectra of, F A Jenkins, 893
Labelling in Public Institutes for the Public, Miss L. E Cheesman, 303
Light : Quanta and Photo-electric Emission, Prof C. G Barkla, 448 , The Convection of, by Moving Matter, C. L R E Menges , The Writer of the Note, 121 ; What is a Beam of ? F. P , 344
Liquid Surfaces, Frictional Forces in, C. T Chase, 724 , L. H G Dines, 894
Long Chain Compounds, On Imperfect Crystallisation in certain, Dr. A Muller, 721
Luminous Leaves and Stalks from Bengal, Prof. S R Bose, 156
Magnesium Hydride Bands, Half-integral Vibrational Quantum Numbers in the, Dr W. W. Watson, 692
Magnetic Storm, The : of January 26-27, 1926, Rev J. P. Rowland, 234 ; of February 23-25, 1926, H. W L Absalom, 416
Manganese Arc Spectrum, A Metastable *P* Term in the, Prof R. A Sawyer, 155
Maori Rock-Carvings, Dr. H. O Forbes, 156
Mathematical Tripos, The, Prof. G H. Bryan, 198
Mendelian Genes and Rates of Development, F. W. Dry, 84
Mercury : Helides, J. J Manley, 587 ; Lines, On the Polarised Emission of, H. W. B Skinner, 418 ; Vapour, The Fluorescence of, H Niewodniczański, 555
Meteors, Detonating, P. Rothwell, 86
Methoca ichneumonides Latr., Parthenogenesis in, H T. Pagden, 199
Microscope Cross-Wires, A Substitute for, F. W. Jane, 724
Miller's Ether Drift Experiment and Stellar Motions, Dr G Stromberg, 483
de Moivre, Abraham, Prof. R C Archibald ; Prof. Karl Pearson, 551 , Prof R C Archibald, 894
Molecules, The Structure of, Prof R T. Birge, 300
Momentum, Conservation of, and the Doppler Principle, Prof. G. E. M. Jauncey, 343
Mullet as an Enemy of the Oyster, Dr J. H. Orton, 121
Muscular Contraction, Prof E. Gorter and F. Grendel, 552
Musical Tone, The Subjective Analysis of, Prof C. V. Raman, 450
Mutant Groups in Nature, *Gentiana campestris* var *alba*, Dr G Claridge Druce, 270
Neutral Molecules, Influence of Electrical Field on the Adsorption of, A Frumkin and A Obrutshewa, 790
New Zealand, Origin of the Fresh-water Fishes of, W. J. Phillipps, 485
Nitric Oxide Molecule, The Energy Levels of the, Dr. Hertha Sponer, 81
Nitrogen . Active, The Nature of, M Duffieux, 302 ; Lord Rayleigh ; E J. B Willey, 381 ; Atoms, Asymmetric, in Natural Products, Prof T M Lowry, 417 ; in the Sun Prof. M. Saha, 268 ; and Stars, F. E. Baxandall, 483 ; Molecule, The Energy Levels of the, Prof R. T Birge, 81
One-Eyed Vision, On, Sir Arthur Schuster, 228 ; Sir Oliver Lodge, 418
Optical Rotatory Dispersion, Prof. T. S. Patterson, 786 , Prof T. M Lowry, 787
Oyster : Mullet as an Enemy of the, Dr J. H Orton, 121 ; Pest ? Is the American Slipper-Limpet (*Crepidula fornicata*) an, Dr J. H. Orton, 304
Ozone and the Upper Atmosphere, Prof H. E. Armstrong, 452
Palaeolithic Drawing of a Horse from Sherborne, Dorset, The, Sir A. Smith Woodward, 86 ; Prof. W. J Sollas , C J Bayzand, 233 ; R E. Steel, 341
Passivity, Catalytic Action, and other Phenomena, Dr. A. S. Russell, 47
Peripatus in England, Birth of, Prof. W. J. Dakin and Miss M G. C Fordham, 858
Petrol-Fields, A Possible Origin of, A F. Lindemann, 159
Phenological Observations and Results in Russia, Prof. P. J. Schmidt, 119
Phenology, International, J. E. Clark, 413, 658 ; F A. Bellamy, 658
Photo-electric Emission, Light Quanta and, Prof. C G. Barkla, 448 ; Photometry, The Use of Arcs and other Fluctuating Sources in, B. Kurrelmeyer, 697 , Polarimetry, Dr J. Kenyon, 304
Photographic Measurements of Buildings or other Structures, Use of an Artificial Horizon in, A. Mallock, 338 ; T. F Connolly, 519
Photometry, Ultra-Violet, Drs G M. B Dobson and D N. Harrison, 724
Pinnotheres veterum, On Nocturnal Colour Change in the Pea-Crab, D. Atkins, 415
Planarian Species, A, new to Britain, Dr. Kathleen E. Carpenter ; H Whitehead and E Percival, 556
Plant as a Measure of the Habitat, The, J. Phillips, 16
Plants, Ecotypes of, Prof. T D A. Cockerell, 588
Polar Front, Greenland or, Prof W. H. Hobbs, 232 ; L C W Bonacina, 451
Polarimetry, Photo-electric, Dr. J. Kenyon, 304
Polarised Light on Bacterial Growth, Effects of, Prof S. S. Bhatnagar and R. B Lal, 302
Pollen-grains, Winged, and Flowering Plants (Angiosperms), J. Parkin, 269
Polyploidy : and Sex Chromosomes, Prof. R. R. Gates, 234 , Dr. J. W Heslop Harrison, 270 , Heterochromosomes and, Dr. J. W. Heslop Harrison, 50
Pondoland, Ancient Coins from, J. F. Schofield, 453
Porphyrin, On a New, H. Munro Fox, 49
Portuguese Oysters be produced on English Oyster Beds by Artificial Fertilisation in the Sea ? Can, Dr. J. H. Orton, 857
Potassium and the Heat of the Earth, Dr. A. Holmes and Dr. R W. Lawson, 620
Primrose Flower, Phyllody in the, F. R Browning, 518
Radiating Masses : The Law of Inertia for, Sir Joseph Larmor, 300 ; The Motion of, and the Effect of Radiation Pressure, Dr J. H Jeans, 376
Radiation and the Elements, Eka-caesium and a Suggestion about, F H. Loring, 448 ; arising from the Mutual Annihilation of Protons and Electrons, Prof A Ll. Hughes and Prof G E. M. Jauncey, 193 ; Intensities, Measurement of, by Photographic Methods, Dr. F. C Toy, 83 , Dr. R. A. Houstoun, 159 , I O. Griffith, 344 ; Note on the Law of, Sir Oliver Lodge, 891 , Resonance, Chemical Effects produced by, Prof. H. S Taylor, A. L. Marshall, and J. R. Bates, 267 ; Dr. E. K Rideal and H. S Hirst, 449 , Pressure, The Motion of Radiating Masses and the Effect of, Dr J. H. Jeans, 376
Re-paging of Reprints : Dr. R H Rastall, 418 , References and, Dr F. A Bather, 516 , E Heron-Allen, 517
Research, The Taxation of, Profs. H. B. Baker and J. Thorpe, 859, 894
Residual Ionisation in Closed Vessels, Dr R W Lawson, 235
Resonance Radiation, Chemical Effects produced by, Prof H S. Taylor ; A L. Marshall and J. R Bates, 267 , Dr E K. Rideal and H. S. Hirst, 449

Rock-lead, Ore-lead, and the Age of the Earth, Dr. A. Holmes, 482
Roget, Peter Mark, and the Voltaic Cell, Miss D. M. Turner, 722
Rosa, The Evolution of, Prof. T. D. A Cockerell, 517
Roy, Major-General William, Sir C F Close, 824
Russia, Phenological Observations and Results in, Prof. P. J. Schmidt, 119
Rustless Steel and Flexible Glass 5000 Years Ago? J. H. Gardiner, 791
Salmon, The Leaping, Dr. D S. Jordan, 85; H. B Walker, 269; W. L. Calderwood, 418
Salts, Complex, Valence Theories and the Magnetic Properties of, D. M Bose, 84
Satellites in the Ultraviolet OH Bands, The Origin of the, Dr. W. W. Watson, 157
Scientific Instruments and apparatus, Neglected Early, Sir D'Arcy Power, 305; Journals, The Disposal of, S, 724
Seasonal Sunshine in Great Britain, J. B. Phillips; C. Harding, 757
Selenium Cells, The Sensitivity of, T. Thorne Baker, 858
Sex Chromosomes, Polyploidy and, Prof R. R. Gates, 234; Dr J. W. Heslop Harrison, 270
Shaping of Wood with Flint Instruments, Experiments in the, J Reid Moir, 655
Signals, The Transmission of, from a Horizontal Antenna, Mary Taylor, 791
Silica, The Action of, on Electrolytes, Dr. A. F. Joseph, 17
Single: Harmonic Wave, Propagation of a, in a Medium in which the Group Velocity and Wave Velocity are the same, A. Mallock, 856; Metallic Crystals, Plastic Deformation of, S J. Wright, 891
Sodium in Comets and in Low Pressure Laboratory Sources, Relative Intensities of the D_1 D_2 Lines of, Prof. H. B. Lemon and N T Bobrovnikoff, 623
Solar Constant, The, and Terrestrial Magnetism, Dr. C. Chree, 46
Solid Alkali Metals, The Magnetic Moment of the Orbit of the Valency Electron of the, Dr. L. C. Jackson, 449
South American 'Linguistics', A Mistaken Attribution in, P. Amaury Talbot, 381
Spectra, the Structure of, Spinning Electrons and, G. E. Uhlenbeck and S. Goudsmit, 264; Prof. N. Bohr, 265; R. de L Kronig, 550; Dr. J. C. Slater, 587
Spiders: Origin of Yolk in the Eggs of, Prof. Vishwa Nath, 693; Spermatogenesis in, and the Chromosome Hypothesis of Heredity, Prof. E. Warren, 82; Prof. J. B. Gatenby, 233
Starch Grains: Hydrolysis of, by Light polarised by Small Particles, Dr Elizabeth Sidney Semmens, 821; Selective Action of Polarised Light upon, Lord Rayleigh; Prof. W. Neilson Jones, 15
Stars, Companion, Names for, Sir Oliver Lodge, 381
Stellar: Diameters, the Determination of, Use of Interference Methods in, M Gheury de Bray, 235; Energy, The Source of, Dr. J. H Jeans, 689
Stimuli in Plants, Transmission of, Prof. U. Ricca, 654; Prof. H. H. Dixon, 791
Stone Age in Ceylon, The, Dr. H. O. Forbes, 589
Strychnine, The Action of, on the Cerebellar Cortex, Prof. F. R. Miller, 486
Sulphur, The Isotopes of, Dr. F. W. Aston, 893
Sun: -fishes, Further Studies of, made during the *Dana* Expedition, 1921–1922, Dr. Johs Schmidt, 80; Nitrogen in the, Prof. M Saha, 268; and Stars, Nitrogen in the, F. E. Baxandall, 483
Surface: Action in Closed Vessels, The Dynamics of, F. H. Constable, 230; Solutions, The "Gas Laws" in, N. K. Adam and G. Jessop, 484, V. Cofman, 755, Tension, The Drop-weight Method for the Determination of, and the Weight of the Ideal Drop, Prof W. D. Harkins, 690
Taxonomic Zoology, The Study of, S. Maulik, 82
Terrestrial Magnetism, The Solar Constant and, Dr. C. Chree, 46
Thermit in Ice-breaking, Use of, Prof. A. S. Eve, 621
Thermopiles, Efficient Use of, A M. Taylor, 892
Time, The Real Meaning of the New Conception of, L. C. W. Bonacina, 456
Uncertainty, Sir Oliver Lodge, 453
Upper: Air Temperatures and Thunderstorms, J. S. Dines, 822; Atmosphere, Electrical Constitution of the, T. L Eckersley, 821; Ozone and the, Prof. H. E Armstrong, 452
Valence Theories and the Magnetic Properties of Complex Salts, D. M Bose, 84
Vesuvius, The Study of Volcanic Activity on, A. Hutchinson, 197
Viscosity of the Blood and Shock, The Relationship between, Dr. R A. Waud, 487
Vision, On One-Eyed, Sir Arthur Schuster, 228, Sir Oliver Lodge, 418
Voltaic Cell, Peter Mark Roget and the, Miss D. M. Turner, 722
Wasteful Research? Prof. H. E. Armstrong, 823
Weather Prediction from Observations of Cloudlets, C. J P Cave; Dr W. J. S. Lockyer, 48; Sir G Archdall Reid, 158, 453, C. D. Stewart, 270
Weight to Height, The Relation of, during Adolescence, D. Caradog Jones, 515; Dr. A. A. Mumford, 656
What we Know, Prof. H. E. Armstrong, 590
Wordsworth's Interpretation of Nature, L. C. W. Bonacina, 304
X-Radiation, The "Modified Scattered," Prof. C G. Barkla and Dr. S R. Khastgir, 228
X-ray: Line Intensities, The Problem of, F. H. Loring, 622; Lines, Relative Intensity of, Y. Nishina and B. B Ray, 121
Zoological Nomenclature, Dr. C. W Stiles, 414

Cosmic: Radiation, Penetrating, L N. Bogoiavlensky, 805, Rays, C. S Wright, 54
Cosmogony, The New, Dr. J. H. Jeans, 134
Cotton. Crop in the Tanganyika Territory, Rules concerning the, 316; Hairs, Measurements of the Reversing Spiral in, Dr. W. L. Balls and H. A. Hancock, 217; in Tanganyika, 529; Some Diseases of, as seen in the Plantations, Dr. W. Robinson, 66
Crepidula fornicata an Oyster Pest? Is the American Slipper-Limpet, Dr. J. H. Orton, 304
Cretaceous Ammonoids of Eastern Australia and Japan, Dr F. W. Whitehouse, 871
Croonian Lecture, The, Prof. A. V. Hill, 809
Crossing of Species Experiments, Prof. E. Ivanov, 135
Crustacea: Normal and Moulting, The Muscles of, J P. Hoet and P. Kerridge, 878; of the Thames Estuary, 870
Crustacean, A Peculiar Parasitic, Prof. T. Komai, 430
Crystal: On the Reflection by a, of its own Characteristic Radiation, W. Duane, 743; The, as Diffraction Grating, D. B. Mair, 157
Crystalline: Form and Chemical Constitution, Dr. A. E. H. Tutton, 508; Lattices of Manganous Fluoride and Manganese Dioxide, Rontgenographic Investigation of the, A. Ferrari, 643; Schists, Some Mineralogical Transformations in, C. E. Tilley, 325; Style: The, and Anaerobic Respiration, C. Berkeley, 518; The Disappearance of the, Dr. C M. Yonge, 691
Crystallisation of Common Things, The Imperfect, Sir William Bragg, 599
Crystals: and Chemistry, 508; during Growth, The Angles of, E. S Hedges, 908; in Metals, Orientation of, 65, large Aluminium, The Distortion of, at Crystal Boundaries, R. L Alston, 34; Mixed, The Radiograms of, G. Friedel, 610, of Iron, Single, On the Magnetic Properties of, Prof. K. Honda, S. Kaya, and Y. Masuyama, 753; of Metals, Production and Properties of large Single, 569; of Potassium Bromide, The Selective Reflection of X-rays by, S K. Allison, 743; of Tungsten, Antimony, Bismuth, Tellurium, Cadmium, Zinc and Tin, Certain Physical Properties of Single, P. W. Bridgman, 569; Self-sounding, F. Seidl, 880; Single Metallic: Plastic Deformation of, W. E. W. Millington and Prof. F. C. Thompson, 720, S. J. Wright, 891; X-ray Analysis of Single, Some Developments in the, R. L. Alston, 34; The Growth of, Prof C. H. Desch, 694
Cupressus macrocarpa × nootkatensis, A. B. Jackson, 364
Cupric Oxide, The Electromotive Behaviour of, R. E. W. Maddison, 252

Curtis's Botanical Magazine, Dr. O. Stapf, 426
Curved Space-time and Radiation, G. Y. Rainich, 811
Cylindrical Functions, Research on, and on certain Analogous Functions, N. Nielsen, 775
Cytoplasm and Chromatin, Prof. C J. Chamberlain, 136
Czeckoslovak Republic, The, and Agriculture, 525

Dacca University, Sir Philip Hartog, 676
Dairy Engineering, J. T. Bowen, 151
Dana Expedition, 1921–1922, Further Studies of Sunfishes made during the, Dr. Johs. Schmidt, 80
Daphnia: A Maleless Race of, which produces Ephippial Eggs, Dr. A. M Banta, 803; The Biology of the Genus, C. Wesenberg-Lund, 775; Experiments on, M. Ramult, 603
Dartmoor Granite, Primary Gold and Silver in the, A. Brammall, 325
Daubeny Laboratory Register, The, 1916–1923; with Notes on Scientific Researches carried out by members of Magdalen College, Oxford, Dr. R. T. Gunther. Vol. 3, 263
Davy Faraday Research Laboratory, The Work of the, Sir William Bragg, 167
Dead Sea Water, Examination of, for Eka-Cæsium and Eka-Iodine, Dr. J. Newton Friend, 789

DEATHS.

Digestive Polypeptides, The Passage of the, into the Portal Circulation and their Arrest in the Liver, J. Cristol, L Hedon, and A. Puech, 402
Dimethylstibine Cyanide, an Analogue of Cacodyl Cyanide, Prof. G T. Morgan, and V. E. Yarsley, 252
Dimolybdomalates, The Polarimetric Study of Mineral and Organic, E Darmois and P Gabiano, 366
Dinoflagellates of Northern Seas, The, Dr. Marie V. Lebour, 79
Dioscorea alata Linn., The Rate of Carbohydrate Transport in, T. G. Mason and C. J. Lewin, 438
Diphenylene Sulphide, Researches on, C. Courtot and C. Pomomis, 708
Diphenylene Sulphide series, Study in the, C. Courtot and C Pomonis, 678
Diphtheria Anti-toxin (T. Madsen and S. Schmidt), The Avidity of, T. Madsen, 775
Dipole Moment and Molecular Structure, Dr. K. Hojendahl, 892
Discovery and Dialectics: Prof. I. Masson, 6; Rev. Dr. R. H. Murray; Prof. I. Masson, 231
Distillation, Industrial: C. Elliot, 334; Principles and Practice of, E. Hausbrand. Translated by Dr. E. H. Tripp, 334
Divalent Metals, The Crystalline Structure of the Fluorides of certain, A. Ferrari, 811
Dodder, Parasitism of the: J Thomson, 210; Mrs M. G. Thoday (Sykes), 452
Domestic: Fowl, On fertility in the, Dr. F. A. E. Crew, 538; Heating: Prof L. Hill, 487; Dr. Marie C. Stopes, 343, 590; Lighting and Heating, M. Gheury de Bray, 198
Doppler: Principle, Conservation of Momentum and the, Prof G E M. Jauncey, 343; Shift, Einstein Shift and, Prof A. S. Eddington, 86
Doublet $K\beta_1$: New Experimental Results concerning the, Dr. G. Ortner, 823, N. Seljakow and A Krasnikow, 554
Do we—don't we—what do we—know? Prof. H. E. Armstrong, 195
Drawing: its History and Uses, W. A. S. Benson, with a memoir by the Hon. W. N. Bruce, 688
Driest and Wettest Years at Individual Stations in the British Isles, 1868–1924, The, J. Glasspoole, 641
Drosera regia (Stephens), A New Sundew, from the Cape Province, Edith L. Stephens, 743
Drosophila virilis. Reddish—a frequently 'mutating' character in, M. Demerec, 402
Drought, its Prevention and Cure, Prof E. H. L. Schwarz, 168
Drygarn and Abergwesyn, Breconshire, Geology of the country between, K. A Davies, 774
Duddell Medal of the Physical Society of London, award of the, to A Campbell, 25
Durham University, Appointments in, 215
Dutch: East Indies, Rainfall of the, 431; Pendulum Observations: in the Atlantic and the Pacific, Dr. J. J. A. Muller, 786; in a Submarine with a New Apparatus, Dr. J. J. A. Muller, 531
Dwi-Manganese: (At. No. 75), The Occurrence of, in Manganese Salts, Prof J. Heyrovský, Dr. G. Druce, 16; In Manganese Salts, The Occurrence of, Dr. V. Dolejšek, Dr. G. Druce, and Prof. J Heyrovský, 159
Dyeing, The Application of the Phenomena of, to the Revivification of Printed or Written Matter removed by Chemical Treatment, R. Mellet and M A. Bischoff, 35
Dyer's Research Medal for 1924–25, awarded to Dr. F. M. Rowe, and a certificate to Miss Clara Levin, 61
Dyestuffs, Dr E F. Armstrong, 676
Dynamics, The Geometry of, J. L. Synge, 502
Dynamo: The, its Theory, Design, and Manufacture, C. C. Hawkins. Sixth edition. Vol 3, 263

Early Science at Oxford, 179
Earth: Structural Features of the, E. B. Bailey, 863; the Age of the, Rock-lead, Ore-lead, and, Dr. A. Holmes, 482; The, and the Stars, Dr. C G. Abbot, 819; The Heat of the, Potassium and, Dr. A. Holmes and Dr. R W. Lawson, 620; The Structure of the, Dr. H. Jeffreys, 78; the Surface-history of the, Eclogite and, Prof J. Joly, 689
Earthquake Shock in Perthshire, 355
Earthquakes: at Murrambateman during March and April 1924, and January to April 1925, L. A. Cotton, 71; in Scotland, 391; The Depth of Origin of, R. D. Oldham, 33
Earth's: Atmosphere, The Uppermost Region of the, Dr. G. M B. Dobson (Halley Lecture), 697; Crust, Investigations of the, 703
Earthworms, Movement of, Effect of Light on the, E. Nomura, 702
Easter Island, A Wood-carving from, H. U. Hall, 245
Echinocardium cordatum, The Development of the Calcareous Test of, I. Gordon, 877
Echinus miliaris, Development of the Calcareous Test of, I Gordon, 217
Echo Soundings in the Indian Ocean, 395
Eclipse: A Homeric, Dr. C Schoch, 282, 496; Observations in Sumatra, January 14, 1926, Lieut.-Col F. J. M. Stratton, 306; of January 14, 1926, Solar Eclipses and the, 128
Eclogite and the Surface-history of the Earth, Prof J. Joly, 689
Ecuador, The closing of the Universities of, 104
Edinburgh University: Appointments in, 32; gift to, by Dr. and Mrs Inglis Clark, 215; Prof E. Shearer appointed professor of agriculture, 501; Inaugural Address of Prof. Lelean, 632; impending resignation of Prof. B. P. Watson, 740; Prof J. A Clark appointed to the chair of Materia Medica, 772; gift to, by T. Cowan, 807, celebration of the bicentenary of the Faculty of Medicine; resignation of Dr. H. Robinson, 912
Edison Medal for 1925, award of the, to Dr. H. T. Ryan, 133
Education: and Tradition in Social Hygiene, Influence of, Prof. P. Nunn, 600; Research in, work of the Committee of the British Psychological Society on, 243; Value for Money in, S. Hey, 250; Visual, F. N. Freeman and others, 584
Eel, The natural immunity of the, against the virus of hydrophobia and the rabicidal action of its serum, Mme. Phisalix, 291
Eels, Fresh-water: (Anguilla), On the distribution of, throughout the World. II., Indo-Pacific Region, Dr. Johs. Schmidt, 466; The Geographical Distribution of, 466
Egg-colour in Birds, Inheritance of, Kopec, 871
Eggs, The Storage of, T. Moran and J. Piqué, 875
Egypt: and the Sudan, suggested scheme for the further irrigation of, 315; offer of gift to, for a museum at Cairo, J. D. Rockefeller, Jr., 279; the Fisheries of, Report on, 1924, Kaimakam G. Jenkins Bey, 499
Egyptian: Archæological work, The proposed gift by J. D. Rockefeller, 562; Archæology, Sir Flinders Petrie, 407; Fisheries, 499; Religion and Ethics, F. W. Read, 407
Egyptians, Ancient, Sir Flinders Petrie, 578
Egyptology in Victorian Dress, 578; Sir Flinders Petrie; The Reviewer, 788
Einstein: Shift and Doppler Shift, Prof A. S. Eddington, 86; Theory, The, explained and analysed, S. H. Guggenheimer, 885
Eiszeitalters, Die Gliederung und absolute Zeitrechnung des, Prof W. Soergel, 113
Eka-cæsium: and a suggestion about Radiation and the Elements, F. H. Loring, 448; and Eka: -iodine, Examination of Dead Sea Water for, Dr. J. Newton Friend, 789; -iodine: and Eka-cæsium, Prof. O. Hahn, 498
Electric: Cables, Insulated, C. J. Beaver. In two parts. Part I., Materials and Design, 852; Circuit-breakers, Control Device for, 764, Discharges, Gaseous Combustion in. Part I., G. I. Finch and L G. Cowen, 469; Field: Drops formed in an, L. Abonnenc, 810; The Mechanics of the, Sir J. J. Thomson, 665; Force, The Intermittence of, Sir J. J Thomson, 70; Induction Furnaces, Dr. Northrup, 396; Salt Bath Furnaces, 498; Supply in Great Britain, 145; Vehicles, C. W. Marshall, 192

Electrical: Accidents and Artificial Respiration, S. Jellinek; d'Arsonval, 254; Communication. I., Line Telegraphy and Telephony, R. P. G. Denman, 850; Engineering: Elementary, a Lecture and Laboratory Course intended for Students preparing for the first National Certificate Examination in Electrical Engineering, Prof. O. R. Randall, 784; Engineers, Institution of, awards of the, 835; Insulator, A New, A. Samuel, 327, Machinery Erection, T Croft, 299; Photometry and Illumination: a Treatise on Light and its Distribution, Photometric Apparatus and Illuminating Engineering, Prof. H. Bohle, 718; State of the Upper Atmosphere, The: Sir Ernest Rutherford and others, 385; Prof. S. Chapman, Sir Henry Jackson, Dr. W. H. Eccles, 454.
Electricity: and Agriculture, Borlase Matthews, 389; and Magnetism, The Mathematical Theory of, Dr. J. H. Jeans. Fifth edition, 12; from Thales to Einstein, The Story of, W. F. F. Shearcroft, 8; and the Structure of Matter, L Southerns, 8; Industrial, Prof. C. L. Dawes. Part II, 888; Readable School, V. T. Saunders, 8; Supply Bill, The, 441; through Gases, Discharge of, Dr. J. S Foster, 197
Electro: chemistry: Principles and Applications of, Prof. J. H. Creighton. In 2 Vols. Vol. I., 479; Principles and Practice of, 479; Theoretical and Applied, Prof. M. de Kay Thompson. Revised edition, 479; -endosmosis, The Influence of Electrolytes in, H. C. Hepburn, 878
Electrode: Arc, A Single, N. R. Davis and C. R. Burch, 342; Potential, The Significance of the, J. Heyrovský, 364
Electrolux Refrigerator, The, 315
Electrolytes: The Action of Silica on, Dr. A. F. Joseph, 17; The Electrode Capacity and Resistance of, for a wide range of Frequencies, B. B. Banerji, 252
Electrometer designed for the Study of Weak Radioactive Manifestations, An, A Nodon, 538
Electron: Spinning, The Dynamics of the, Prof. A. W Conway, 742; The, its Isolation and Measurement and the Determination of some of its Properties, Prof R. A. Millikan. Second edition, 8
Electronic: Orbits on the Relativity Theory, Q. R. Baldwin and Prof. G. B. Jeffery, 363; Structure and Band-spectrum Structure in Diatonic Molecules, Systematic relations between. 3 Parts, Prof. R. S. Mulliken, 743
Electrons: Atoms and Molecules, Prof. T. M. Lowry, May 29, Suppt., 33; Diffusion of, G. Glockler, 743; Spinning: Prof. A. S. Eddington; Prof. F A. Lindemann, 652, Dr. J. Frenkel, 653; and the Structure of Spectra: G. E. Uhlenbeck and S Goudsmit, 264; Prof. N. Bohr, 265; Dr. J C. Slater, 587; R. de L. Kronig, 550; The Motion of the, L. H Thomas, 514; through Small Apertures, The Passage of, G. F. Brett and Prof. R. Whiddington, 365
Elements: of Atomic Numbers 75, 85, 87, and 93 by means of X-rays, Foreshadowing, F. H. Loring; Adam Hilger, Ltd, 153; The Writer of the Note, 154; of Different Valency, Solid Solutions between Compounds of, G. Bruni and A Ferrari, 367; The Transmutation of: Dr. A. C. Davies and Prof. F. Horton, 152; Prof. A. Smits, 620; A Transmutation of Lead, Prof. A. Smits, 19
Embryo, the Organisation of the, G. R. de Beer, 706
Empetrum, The Genus, R. D'O. Good, 774
Empire Mining and Metallurgical Congress, The, to be held in Canada in 1927, 318
Endemism, The Origin of, A. A. Lawson, 181
Endocrine Organs, Human, The Histology of the more important, at various Ages, Dr. Eugenia R. A. Cooper, 582
Engineer: Officers in the Royal Navy, The Status of, 460
The, and the Prevention of Malaria, H. Home, 751
Engineering: A History of, A. P. M. Fleming and H. J. Brocklehurst, 75; The Advancement of, in relation to the Advancement of Science, Prof A. E. Kennelly, 160.
English: Channel, Hydrography of the, H W Harvey, 245; Gypsy Folk Medicines, T. W. Thompson, 907
Ensor's Comet, 393, 428, 566
Entomology: Applied, Dr. P. A. Buxton, 623; Past and Present, H. J. Carter, 811
Enzyme Action, Dr E. K. Rideal, 510
'Eolith' Factory, An, 602; J Reid Moir, 723
Erde, Der Aufbau der, Dr. B Gutenberg, 78
Eskimo, Origin of the, K. Rasmussen, 394
Ether Drift Experiments: Prof. D. C. Miller, 890; On Prof Miller's, Sir Oliver Lodge, 85[illegible]
Ethnic Relations in India and the Near East, L. H. Dudley Buxton, 639
Ethnographical Studies and Colonial Administration, 745
Ethylene: and Chlorine, The Reaction between, Stewart and Fowler, 908; Linkage, Polar form of, H. Gilman and J. M. Peterson, 498; Oxide, The Catalytic Hydrogenation of, P. Sabatier and J F. Durand, 642; with the Halogens, Influence of Surfaces on the Combination of, R. G. W. Norrish, 401
Eugenics: Annals of. Vol. I., Parts 1 and 2, 645; National, 645
Euler's Constant, The Arithmetical Nature of, P. Appell, 774
Euphausids, Numerical Reduction of Instars in the Metamorphosis of, R. Macdonald, 894
European: Civilisation, The Origin of, V. Gordon Childe, 716; Corn Borer in the United States, R. H. Pettit, 567; Literature: A Dictionary of, designed as a Companion to English Studies, Laurie Magnus, 616.
Everest: The Fight for, 1924, Lt.-Col. E. F. Norton, and others, 446
Evolution: and Biology, Prof. R. R. Gates, 716; and Creation, Sir Oliver Lodge, 779; and Genetics, Prof. T. H. Morgan, 716; A Taxonomic Study in, F. W. Pennell, 603; The Botanical Case for, Dr. D H. Scott, 316; The Species Problem and, O. W Richards and G. C. Robson, 345, 382
Experimental: Biology, Society for, Conference by the, 133; Results, A New Method of Studying: A. Bemporad, 643; M. Cantone, 402
Exploration, Adventures of. Book 4, Africa, Sir John Scott Keltie and S C. Gilmour, 752
Explosive, On the Pressure-wave sent out by an, W. Payman and H. Robinson, 568
Extra Pharmacopœia, The, of Martindale and Westcott. Revised by Dr. W. H. Martindale and W. W. Westcott. Eighteenth edition. Vol. 2, 151

Faraday: Cylinder, Does a, measure Electron Currents, E. O. Lawrence, 465; The Rôle of the, in the Measurement of Electron Currents, E. O. Lawrence, 403; medal of the Institution of Electrical Engineers, award of the, to Col. R. E. B Crompton, 170; *Society, Transactions of the*, in future to be published bi-monthly, 600
Farm Book-keeping: Principles and Practice of, a Text-Book for Agricultural Students, L. F. Foster, 548
Fats, Synthetic, Nutritive Value of, 805
Fatty Acids, Mixtures of, Application of Capillary Measurements to the Study of, R. Dubrisay, 218
Fauna: of the Chatham Islands, The, E. Meyrick, and others, 739; of the Empire, Society for the Preservation of the, Work of the, 423; of the Sea Bottom, Quantitative Studies on the, No. 2, F. M. Davis, 533
Faune de France: 10: I., L. Berland, 511; 11: Abbé J.-J Kieffer, 12: E. Séguy, 686
Fayum, Research in the, Miss Gertrude Caton-Thompson and Miss Elinor W. Gardiner, 701
Fenugreek, The Composition of the Seed of, and its admixture with Wheat intended for Milling, E. Fleurent, 708
Fermente, Die, und ihre Wirkungen, Prof. C. Oppenheimer, Physikalische Chemie und Kinetik, Dr. R. Kuhn Funfte Auflage, 510
Fern: and an Alga, The Symbiosis of a, A. Limberger, 804, Prothalli, Regeneration of, K. Linsbauer, 603
Ferns, A Scheme of Phyletic Grouping of, Prof. F. O. Bower, 437
Ferrites, The Thermomagnetic Study of some, H. Forestier and G. Chaudron, 611
Ferromagnetics, The Atomic Moments of, E. C. Stoner, 305

Ferro-nickels, artificial, and a Nickel Iron of meteoric Origin, Some Relations between, M. Peschard, 35
Ferrous Alloys with Aluminium, The Cementation of, J. Cournot, 610
Fertilisation in a Cycad, Prof. A. A. Lawson, 465
Ficus edulis and *Euphorbia striata*, On two Protozoan Parasites found in the Latex of, Prof. H. B. Fantham and Dr. Annie Porter, 290
Field Museum, Chicago, publications of the, 765
Fiji, Megalithic Works in, J. Hornell, 320
Films, Thin, The Structure of. Pt. 7, N. K. Adam and G. Jessop, 179
Filterable Viruses, Ultramicroscopic Organisms of, Prof R. R. Gates, 692
Filter-passing Viruses, Problems of Immunity and Infection, 293
Fine: Cotton Spinners and Doublers Association, Ltd., Prof. F. P. Slater appointed chief of the experimental department of the, 61, Measurement, Art of, Some Recent Developments in the, J. E. Sears, jun, 764
Fireball on April 9, W. F. Denning, 633; on May 2, W. F. Denning, 766
Fireballs, Two, W. F. Denning, 496
Firedamp: Electric Ignition of, Prof. R. V. Wheeler, 737; Inflammability of, in the Presence of Black-damp, H F. Coward and F. J. Hartwell, 769
Fisheries, Fluctuations in, B. Storrow, 602
Fishes: Colour Changes of, Influence of Chemicals on the, L. Abolin, 574; Freshwater, The Distribution of, Sir Herbert Maxwell, 719; Morphology of, Prof. F. H. Edgeworth; E. P. Allis, 837; The Hyomandibula of, Prof. F. H. Edgeworth, 284; Young, Dr. A. C. Johansen, 464
Flagstaff, Arizona, An Archæological Collection from, J. W. Fewkes, 528
Flexible Glass, Rustless Steel and, 5000 years ago? J. H. Gardiner, 791
Flora of the Presidency of Madras, J. S. Gamble. Part 7, 785
Flower Colour Factor and Self-sterility Factors, Linkage between a, F G Brieger and A. J. Mangelsdorf, 811
Flowering Plants: The Families of. I.: Dicotyledons, J. Hutchinson, 478; The Phylogeny of, J. Parkin, 478
Fluids under High Pressure, A Device for circulating, J. R. McHaffie, 438
Fluorine, An easy Method for the Preparation of, P. Lebeau and A. Damiens, 218
Flying Shadows, Recent Theories of, V. Ronchi, 679
Flysch Problem, An attempted Solution of the, O. Abel, 367
Fœtal Ossification, M. Kupfer and H. R. Schinz, 634
Food: and Health, Prof. R. H. A and Violet G. Plimmer, 44; Health, and Strength, Inter-relationship of, Sir Arbuthnot Lane, 733; Investigation Board, Report of the, for the Year 1924, 481; The Preservation of, 481
Foot-and-Mouth Disease, Fresh Carcases as a source of, 833
Foraminifera, The Classification of the, J. A. Cushman, 136
Forecasting, Long-range, Sir Gilbert Walker, 670
Forestry: Development, Recent, W. L. Taylor, 131; Education at the Universities, 389
Formosa, The Head-hunters of, Mrs Janet B. M. McGovern, 536
Fossil: Insects in Relation to Living Forms, Dr. R. J. Tillyard, 828; Men of Denise, near Le Puy-en-Velay, A Summary Anthropological Examination of the, L. Mayet, 915; Plants, New Technique with, T. M. Harris, 670
Fossils: of the Middle Lias collected by the Charcot Expedition at Cape Stewart, Jameson's Land, East Greenland, E. Haug, 401; The Relative Age of Rocks containing, Sir Arthur Smith Woodward, 21
Fowl, Domestic, The Relation of Gonadic Structure to Plumage Characterisation in the, A. W. Greenwood and Dr. F. A. E. Crew, 436
France: Faune de, 11, Abbé J.-J. Kieffer; 12, E. Séguy, 686, Geophysical Observations in, 639
Franklin Institute: award of the John Price Wetherill medal to F. Twyman and the Edward Longstreth medal to T. Midgley, 318; *Journal of the*, centenary of the, 282
Frequencies, Three Fundamental, M. Home, 194
Freshwater Fishes: of New Zealand, Origin of the, W. J Phillipps, 485, The Distribution of, Sir Herbert Maxwell, 719
Freud, Prof. S., seventieth birthday and work of, 629
Frictional Forces in Liquid Surfaces, L. H. G. Dines, 894
Friction in a Vacuum? Did Davy melt Ice by, Prof. F. Cojori, 519
Fringes due to Cold Hardening or Corrosion, The, A. Portevin, 439
Fritz, John, gold medal, The, presented to E. D. Adams, 565
Frogs and Toads, On the Nuptial Pads of, from the Lamarckian Point of View, J. T. Cunningham, 774
Fruit: and Fruit Growing, 259, The Sea Transport and Storage of, Prof. J. McLean Thompson, 801; The Preservation of, Prof. B. T. P Barker and O Grove, 100; Trees, The Chlorosis of, T. Wallace and C. E. T. Mann, 767
Fruits, Hardy, A Handbook of, more commonly grown in Great Britain: Stone and Bush Fruits, Nuts, etc., E. A. Bunyard, 259
Fuel: Research: Board, Report of the, 1924, 594; H. J. Hodsman, 594; Technology, Suggested Organisation of an Institution of, 391
Fulminating Material, The Study of, E. Mathias, 254, 327
Fumaria and Rupicapnos, H. W. Pugsley, 573
Fundamentalism and Science, Rev J. C. Hardwick, 42
Fungi, Comparative Morphology of, 820
Fungus Rings, Rate of Growth of, J. Ramsbottom, 158
Fusarium, The Action of certain Enzymes of, C. Sibilia, 611

Galileo Skull, The Finding of the, Rev. T. Crouther Gordon, 438
Gammarus chevreuxi, Sexton, New Mutations in, Mrs. E. W Sexton and Miss A. R. Clark, 194
Garnet in Pelitic Contact Zones, On, C. E. Tilley, 537
Gas: Industry, Coal Conservation and the, Prof. J. W. Cobb, 51; Ions in HCl Mixtures and the Nature of the Ion, The Mobility of, L. B. Loeb, 403; 'Laws,' The, in Surface Solutions, N. K. Adam and G. Jessop, 484
Gasanalytische Methodik des dynamischen Stoffwechsels, Die, Dr W. Klein und Maria Steuber, 785
Gaseous: Combustion at High Pressures. Part VI., Prof. W. A. Bone, D. M. Newitt, and D. T. A. Townend, 324; Explosions, Infra-red Emission from, Dr. W. E. Garner, C. H. Johnson, and S. W. Saunders, 790; Ions in HCl Gas and HCl Air Mixtures, The Mobility of, L. B. Loeb, 403; Reactions, Unimolecular and Bimolecular, A Comparison between, C. N. Hinshelwood and W. K. Hutchison, 842
Gases: Coloured, A Method of Estimating, H. Copaux and A. Copaux, 218; Flow of, at High Speeds, Dr. T. E. Stanton, 841; On the Ignition-point of, at Different Pressures, Prof. H. B. Dixon and W. F. Higgins, 30; On the Firing of, by Compression, Prof. H. B. Dixon and J. Harwood, 30, spontaneously evolved from some Thermal Springs of Madagascar and Réunion, The Composition (ordinary and rare gases) of the, C. Moureu, A. Lepape, H. Moureu, and M. Geslin, 574; The Dynamical Theory of, Dr. J. H. Jeans. Fourth editions, 299; The Ignition-point of, and its relation to Volume and Pressure, 30; the Ions in, The Mobility of, M. Laporte, 611; the Specific Heats of, On the Determination of, at Constant Pressure and at Constant Volume, and their Ratio by Adiabatic Expansion, Prof. C. H. Lees, 842
Gastric Secretion of Birds, Changes in the, P. J. Kaas, 769
Gaz nobles, L'Hydrogène et les, Dr. J. J. Van Laar, 116
Gems and Gem Materials, Prof. E. H. Kraus and Dr. E F Holden, 752
Genes and Linkage Groups in Genetics: C. Tate Regan, 86, 341; Prof. J. S. Huxley, 154, 268; Prof. E. W. MacBride, 232, 340; Prof. R. C. Punnett, 514

Genetics: Genes and Linkage Groups in: C Tate Regan, 86, 341, Prof. J S Huxley, 154, 268, Prof. E. W. MacBride, 232, 340; Prof R. C Punnett, 514, Principles of, an Elementary Text, with Problems, Prof. E W. Sinnott and L C Dunn, 336
Genève, Société Botanique de, Dr G. Claridge Druce elected a corresponding member of the, 61
Gentiana campestris var. alba, Mutant Groups in Nature, Dr. G Claridge Druce, 270
Geodetic Observations in the U S A, 140
Geographical Association. Annual Meeting of the, 139, gift to the, by the Carnegie Trust of the United Kingdom, 61
Geological Age of the Earth, The, Prof J Joly, Dr A. Holmes, 592; Congress, The, and Museums, Dr. F A. Bather, 199, Society of London: awards by the, 169, David-Pidgeon Fund, Proceeds of the, awarded to Dr. D Williams, 527, election of officers, 355, Time, The Measurement of, Prof. A C Lane, 210
Geology: American, Trends in, Dr W C. Mendenhall, 489; Economic, Prof. H Ries. Fifth edition, 688, of India. for Students, D. N Wadia. Second edition, 718
Géométrie du compas, A Quemper de Lanascol, 149
Geometries, On various, giving a Unified Electric and Gravitational Theory, J M. Thomas, 743
Geometry: A School, on 'New Sequence' Lines, W. M Baker and A A. Bourne, 12; Associated with the Double Binary (2·2) Form, A, W Saddler, 538; Exercises in, V Le Neve Foster. Part I., 116; The New Matriculation, A G Cracknell and G. F Perrott, 12, for Beginners, as far as the Theorem of Pythagaros, J. G. Bradshaw, 79; Higher, 149; Principles of, Prof. H F. Baker Vol 4, Higher Geometry, 149
Geophysical Observations in France, 639
Geophysics and Meteorology, Journal of Vol I., No 2, 800
Geostrophic Winds, On the Dynamics of, Dr. H. Jeffreys, 33
Geostropism, Observations on, D Greenwood and Dr. W. H. Pearsall, 365
Gerlach and Stein's Magnetic Experiments, Intensification of the Metallic Image in, Dr J. H. J Poole, 451
German: Chemical Industry, The, 241; Outwash Terraces, The, and the Astronomical Theory of the Ice Age, W B. Wright, 113
Germany, Electrification in, 902
Germinal Gland, On the Function of the, before Puberty, Experiments on Rats, B. P. Wiesner, 143
Gibbs, Willard, medal of the American Chemical Society, award of the, to Sir James C Irvine, 835
Glacial Geology of the Southern Uplands of Scotland, West of Annandale and Upper Clydesdale, The, J. K Charlesworth, 253
Glaciation of the Present Tropics, The Meteorological Conditions during the, C. E. P Brooks, 641
Glasgow University, Dr. R. H. Thouless appointed lecturer in psychology, foundation of a lectureship and medal in commemoration of Sir William Macewen, 640
Glass: British Chemical, Prof. E B. Poulton, 381; Chemical Composition of, Relationship between the Durability and the, Violet Dimbleby and Prof. W. E. S Turner, 70, Research Association, Work of the, 398; Suitable for use with Automatic Machines, The Composition of, Prof W E. S Turner, 70, The Annealing and Reannealing of III, W. M. Hampton, 364; The Early Manufacture of, Sir Flinders Petrie, 834, The Nature of the Polishing Operation, F. W. Preston, 364; Transparent Quartz, The Manufacture of, H George, 642
Glauconite, The Constitution of, A. F. Hallimond, 453
Glucose, Oxidation and Storage of, under the Action of Insulin, C. H Best, Prof. H H. Dale, J. P. Hoet, and H. P Marks, 678
Glucosides Hydrolysable by Rhamnodiastase, The Biological Method of Research, in Plants, on, M. Bridel and C. Charaux, 254
Glycerol, The Crystallisation of, M. O. Samson, 642
Glycogen, The Use of, in the Preparation of Colloidal Metals, J Hugounenq and J. Loiseleur, 642
a-Glycols, The Dehydration of the, A. Favorsky and Mlle. A. Tchilingaren, 327
God. and Evolution, I Believe in, Prof. W. W Keen Fourth edition, 779, Ideas of, in the Religions of the World, 111; The Attributes of, the Gifford Lectures delivered in the University of St. Andrews in the year 1924–25, Dr L R Farnell, 111
Gold in the Dartmoor Granite, Dr A. Brammall, 670
Goldsmiths' Company, Prime Warden of the, Sir Dugald Clerk elected, 835
Golf Links The Professor on the, some Sidelights on Golf from Modern Science, C. W. Bailey, 585
Gordius, The Life-history of, Dr J Švábenik, 136
Graduation, On the Theory of, A. C. Aitken, 70
Grains of Wheat, The Possibility of determining the Age of, by the Temperature of their Germination, O. Munerati, 439
Grand Canyon, Fossil Footprints from the, Dr. Gilmore, 498
Graphite, Structure of, G Asahara, 359
Grapes, Ripening of, Decrease in Acidity during the, P R v. d R Copeman, 70
Grass Rusts of South America, J C. Arthur, 28
Gravitational Fields, Static and Isotropic, G. Temple, 878
Great: Britain: Broadcasting in, 473; Seasonal Sunshine in, C Harding, 422; Ouse Basin, The Pleistocene Deposits of the Lower Part of the, Prof J E. Marr, 573
Greece, Prehistoric, and Mother-right, Dr H J Rose, 630
Greenland: or Polar Front: Prof W. H Hobbs, 232, L C. W Bonacina, 451, the Flora of, On the Origin of, C. H Ostenfeld, 775; Western, The Cretaceous Plant-bearing Rocks of, Prof A. C. Seward, 217
Greenlanders, The Fisheries of the, Prof. A S Jensen, 245
Greenwich Sidereal Clock, The New, W. Bowyer, 98

Haddock and Whiting in Icelandic Waters, Age and Growth of, B Saemundsson, 669
Hæmatological Differentiation, The Principles of, A. Piney, 536
Hæmatolysis and Hæmatopoiasis at very High Altitudes and in Air experimentally Rarefied, R. Bayeux, 254
Hæmolytic Reactions, The Equations applicable to Simple, E. Ponder, 878
Hahnemann, Samuel, as a Chemist, Prof. E. Q von Lippmann, 396
Hair in Man, The Significance of the Character of the, Dr. F. Sarasin, 357
Halides, Electrometric Titration of, W. Clark, 872
Halley Lecture, The, Dr. G M. B. Dobson, 697
Halo, A very rare, C. J. P. Cave, 791
Hamburg Observatory, The, Bergedorf, Report for 1924, 601
Hardness: A. Mallock, 117; The Measurement of, by the Pendulum, P Le Rolland, 810
Harvest Spiders of Ireland, The, D R. Pack-Beresford, 742
Haute-Dordogne, The Coal Basin of, G. Mouret, 471
Hayden Memorial gold medal, The, awarded to Prof W. B Scott, 565
Health: and Empire Part I, 599; and Environment, Prof. L Hill and A Campbell, 852
Heart, Early Embryonic, Beating of the, P N Johnstone, 528, -lung Preparation, A Closed-circuit, J. de B. Daly, 142, The Beats of the, and the other Sounds of Auscultation, The Amplification Collective Audition of, G. Lafon, 879
Heat. An Elementary Text-Book, Dr I. B Hart, 261; The Kinetic Theory of, 225; the Mechanical Equivalent of, The Determinations of, Prof. T. H. Laby, 326
Heating, Domestic: Prof. J. B. Cohen, 658, Dr. Margaret Fishenden, 666
Heaviside Layer, The Constitution of the, T. L. Eckersley, 380
Hebrew University of Jerusalem, Department of Hygiene, Dr. I. J. Kligler appointed head of the, 706
Hebrides, Geology of the. Part 3, Dr. T. J. Jehu and R. M. Craig, 253
Helium: Excited, Absorption and Resonance Radiation of, W. H McCurdy, 122; in Canada, Prof. J. C. McLennan, 93; Protons in, The Free Path of, Prof. A. J. Dempster, 575; Structure of the D_3 Line of, On the, W. A. MacNair and W. H. McCurdy, 159; Terrestrial, The Origin of, and its Association with

other Gases, S C. Lind, 182; (ii) The Density and Atomic Weight of, P. Baxter and H W Starkweather, 402; The Free Path of Slow Protons in, Prof. G. P. Thomson, 235
Helminths, Three New, H. O Monnig, 743
Hendersonia, Anatomy of, H. B. Baker, 464
Hephæstus: or, The Soul of the Machine, Dr. E. E. Fournier d'Albe, [illegible]12
Heptagon, Regular, The Scientific Construction of the, with Angles correct to ten seconds, derived from two Crossed-parallelograms of a Semi-ellipse, Prof. T. Alexander, 466
Herbal: of Apuleius Badbarus, The, from the early Twelfth-century Manuscript formerly in the Abbey of Bury St Edmunds, described by Dr R. T. Gunther, 617; The Earliest, written in England, 617
Herbarium Organisation, Dr. Millspaugh, 765
Herepathite, A new Method of Production of, A. Zimmern, 843
Herring: W. C Hodgson, 284; Investigations: B. Storrow and Mrs. Cowan, 99, Frequency Curves in, Dr E. Lea, 635
Herrings: of the Eastern Part of the English Channel, The, W C. Hodgson, 342; on the Welsh Coast, E. E. Watkin, 767
Hertfordshire, The Natural History of, Dr. A. Wilmore, and others, 371
Heterochromosomes and Polyploidy, Dr. J. W. Heslop Harrison, 50
Hevea Brasiliensis, "Mouldy Rot" in, F W. South and A Sharples, 28
Hexosamines and Mucoproteins, Dr. P. A. Levene, 851
Hexosephosphoric Acid Esters in the Mammalian Organism, The Fate of the, 434
High: Frequency Current; Unidirectional, Physiological Effects, Cluzet and Chevalier, 35; Temperature Standards, 671; -voltage Discharges, Distribution of Electric Force in, A. E. M Geddes, 253
Highway Materials, Sampling and Testing of, Prof. W. H. Barton, Jr., and Prof. L. H Doane, 650
Hindu Observances, Some, Dr. Elsie Clews Parsons, 28
History, The Study of, 646
H M. Dockyards, awards to apprentices in, 68
Ho-kien and Tamil Skulls, A Study of, G G. Harrower, 181
Holomorph Function, Certain Developments of a, N. Nielsen, 775
Hop, Diseases of the, Prof. E. S. Salmon, W M. Ware, and others, 67
Horse and Man, Sympathetic Training of, Major T. S Paterson, 549
Hours, Wages, and Welfare in Industry, W. H. Coates, 799
House-fly, The. Second Edition, Major E. E. Austen, 906
H-rays from Paraffin and Aluminium, The Photographic Action of, Fraulein M. Blau, 29
Human: Endocrine Organs, Histogenesis of, 582, Skull, Remains of an Ancient, found at Gibraltar, Miss Garrod, 905
Humanism, Science and, 109
Humanities, The Science of the, 618
Humidity in Closed Spaces, Measurement of, Dr. Ezer Griffiths, 604
Huxley Memorial Medal, The, of the Royal Anthropological Institute awarded to Dr. A. Hrdlička; the Huxley memorial lecture for 1927 to be delivered by Dr. Hrdlička, 564
Hyacinth, Chromosomes of, C. D. Darlington, 670
Hybridity, Parthenogenesis, and Segregation, A. D. Peacock and Dr. J. W. Heslop Harrison, 378
Hydraulic Cements, The Theory of Hardening of, Baykoff, 290
Hydrocarbon Mixtures, The Adiabatic Ignition of, A. Pignot, 401
Hydrogen: and Helium Spectra, Interpretation of the, J. C. Slater, 181, and Potassium Chloride, Conductivities of, T. K. Brownson and F. M Cray, 211; as Anion, Prof. G. N. Lewis, 824; -Bigamous, a Protest, Prof. H. E. Armstrong, 553; Capture of Electrons by α-Particles in, J C. Jacobsen, 858; Chloride and similar Gases, The Quantum Theory of the Dielectric Constant of, L. Pauling, 403, Critical Potentials; and the Heat of Dissociation of, as Determined from its Ultra-violet Band Spectrum, E. E. Witner, 811, in the Presence of Catalytic Nickel and Copper, J. H. Wolfenden, 363, Cyanide, Vapour Pressures of, 568, Doublet, The, Dr. W. V. Houston, 590; Exponent of Water, The, A. Kling and A Lassieur, 218; in Gaseous Mixtures, The Estimation of small Quantities of, P. Lebeau and P. Marmasse, 843; Overpotential, Evidence for a Film Theory of, from Surface Tension Measurements, A. L. McAulay and F. P. Bowden, 363, Peroxide, The Decomposition of, in the Presence of certain Hydroxides in Suspension, Mlle. Suzanna Veil, 810; Spectrum, Secondary, Structure in the (IV.), Prof. O. W. Richardson, 913; The Absorption of, by Palladium and by Palladium Silver Alloys, F. Kruger and A. Sacklowski, 29; The Electrolytic Method of Production of, A. E. Knowles, 96; The Production of, by Micro-organisms, Dr. A C Thaysen, 96
Hydrogenation of Organic Substances at a High Temperature and under High Pressures in the Presence of Non-hydrogenating Catalysts, The, A. Kling and D. Florentin, 402, 439
Hydrography and Plankton at Millport, 735
Hydrolysis: of Proteins, The Isolation of some Undescribed Products of, S B. Schryver and H W. Burton, 436; The Variations of the Constant of, with the Concentration of Sugar, H. Colin and Mlle. A. Chaudun, 610
Hydromechanics, A Treatise on, Dr. W. H. Besant and A. S. Ramsey. Part I.: Hydrostatics. Ninth Edition, 718
Hygroscopic Crystals, Condensation of Water from the Air upon, Dr. J S Owens, 251
Hyperspace Harmonic Analysis Problems introducing Extensions of Mathieu's Equation, Some, P. Humbert, 538
Hypophysis in the Circulation, The Harmone of the, A. Krogh, 775

Iberian Peninsula, The Prehistoric Cultural Provinces of the, Bosch-Gimpera and L. Pericot, 245
Ice: -breaking, Use of Thermit in, Prof. A. S. Eve, 621; Did Davy Melt, by Friction in a Vacuum? Prof. F. Cajori, 519; in the Baltic, 736
Iceland, The Petrology of, Part I, The Basic Tuffs, M. A Peacock, 914
Identification by Recognition, 135
Ilford Electrical Substations, The, 597
Illinium, The Element of Atomic Number 61, J A. Harris, L F. Yntema, and Prof. B. S Hopkins, 792
Illinois River and Peoria Lake, Changes in the bottom Fauna of, R. E. Richardson, 803
Illumination: and Photometry, Standards in, P. Good, and others, 397; Intensity of, and Photochemical Change, F Briers, D L. Chapman, and E Walters, 805
Immunity and Infection: Problems of, the Filter-passing Viruses, 293
Imperial: College of Science and Technology, F Balfour-Browne appointed professor of entomology in the, 535; College of Tropical Agriculture, Prospectus of the, for 1926–27, 178; Government help towards the, 250; gifts to the, 468; Dr. H. R Briton-Jones appointed professor of mycology in the, 535, Development, Radio Communication, and, Dr. W. H Eccles, 659; Forestry Institute, Oxford, Report of the, 632
Inanition, Certain Pathological Changes resulting from, A D Stammers, 743
India: Agriculture in, appointment of a Royal Commission on, 526; and the Near East, Ethnic Relations in, L H. Dudley Buxton, 639; and the Pacific, Capt. A. M. Hocart, 99; Botanical Survey of: Report of the, 1924–25, 494, and Royal Botanic Garden, Calcutta, C C. Calder appointed director and superintendent of the, 61; British, appointment of a Royal Commission on the present conditions of Agricultural and Rural Economy in, 166; Ethnographic Research

in, R E. Enthoven, 400; Education in, in 1923–24, 535, Forestry Research: in, 204, and Education at Dehra Dun, 424; Geology of, for Students, D N Wadia Second edition, 718, Inspector-General of Forests, A Rodger to be, 494; Irrigation in, 135; Mineral Production in, 56, North-west, probable weather in, in January, February, and March, J H Field, 316; Prehistoric Discoveries in, Sir John Marshall, 355; rejection of a vote to the Institution of Archæological Research Fund, 460, Sumeria and, Mackay, 64; the Administration of, the Meteorological Department of the Government of, Report on, J. H Field, 732
Indian: Bird Life · or the struggle for existence of Birds in India, D. Dewar, 851, Botany, 225, Cottons, Waxes of, L. V Lecomber and M E Probert, 28, Fishes, The Swim Bladder of some, D R. Bhattacharya, 701, *Journal of Psychology*, No 1, 699, Museum, Caridea in the, Dr S Kemp, 209, Science Congress at Bombay, The, 704, Services, Recruitment for, 777
Indium, Separation of, 359
Induction Furnaces, High-frequency or 'Ironless,' 760
Industry: and Trade, Committee on, Survey of Industrial Relations, etc, 710; Hours, Wages, and Welfare in, W H Coates, 709; Science in, 681
Inertia, The Law of, for Radiating Masses, Sir Joseph Larmor, 300
Information, A Clearing House for, J G Pearce, 631
Infra-red. Absorption of the N-H Bond, E O Salant, 575; Spectrum of a Diatomic Gas, Relative Intensities of Band Lines in the, Prof E C Kemble and D G Bourgin, 789
Inorganic Analysis, Qualitative, Dr D. R. Snellgrove and Dr J. L White, 785
Insect. Drift, The Physical Basis of, E P. Felt, 754, Pests: in American Agriculture, Dr L O Howard, 497; in Agriculture, The Control of, Dr A D Imms, 248, Report on the Occurrence of, on Crops in England and Wales, 1922, 1923, and 1924, 248
Insects: Injurious, Manual of, Prof G W. Herrick, 888; Moulting of, C Macnamara, 282, The Classification of, T. B. Fletcher, 529; The Sense Organs of, Dr R E. Snodgrass, 638
Insulin. Crystalline, J. J. Abel, 575, On the Effect of, on the Dextrose Consumption of Perfused Skeletal Muscle, C H Best, 142; The Standardisation of, H P. Marks, G A Harrison and R D. Lawrence, 286
Interchange of University Teachers and Students, Dr A Hill, 177
Interference: Bands, F Wolfers, 247, Methods in the Determination of Stellar Diameters, Use of, M. Gheury de Bray, 235
Interferometer Patterns due to the Primary Aberrations, The, R Kingslake, 326
Interstellar Space, Diffuse Matter in (Bakerian Lecture), Prof A S Eddington, 770
Intestinal Flagellates in Tropical America, Prof R W. Hegner, 603; Parasites of Ruminants, M. J Triffitt, 907
Intracellular Oxidation-reduction potential and anaerobiosis, J Needham, 470
Invariant Theory of Forms in Six Variables relating to the Line Complex, The, Prof H W. Turnbull, 538
Invention, British Science and, Ll. B Atkinson, 369
Ion-association, Studies on (1), N. Bjernum, 775
Ionised Oxygen (O II), An Interpretation of the Spectrum of, R. H Fowler and D. R. Hartree, 502
Ions: in Air, The Mobility of. Parts 1 and 2, Prof. A. M Tyndall and G C Grindley, 180, in Gases, The Measurement of the Mobility of, M Laporte, 574, hydrogène de l' eau de mer, La concentration en—le pH · méthodes de mesure; importance océanographique, géologique, biologique, R Legendre, 260; of one and the same Element, Comparison between the Diameters of the, but with different charges, A Ferrari, 679
Iridium from Iron, The Separation of, W. R Schoeller, 809
Iron: A Second Spark Spectrum of, L and E. Bloch, 810; and Steel Institute, Award of Carnegie scholarships, 835; Atom: The Fundamental Level of the, Prof. N K Sur, 380; O. Laporte, 721, Bivalent, A Supposed Nitro-prusside of, L Cambi, 471, contained in Wine, The Oxidisibility of the, J. Wolff and L. Grandchamp, 218, in Antiquity, Dr J. Newton Friend, 834, 862, -iron Sulphide Alloys, B Bogitch, 327; Single Crystals of, Magnetic Properties of, W L Webster, 859; The Determination of very small quantities of, H. L Smith and J H Cooke, 809; the Electrolytic Corrosion of, The Influence of Alternating Currents in, Prof A. J Allmand and R H D Barklie, 437
Ironbarks and Allied Woods, Identification of the principal, M B. Welch, 71
Irrigation in India, 135
Isis, December, 425
Isodora africana (Krauss), and closely allied Species, Variations in the Shells of, F. G Cawston, 743
Isolated Magnets, The Observation and Measurement of very small, F Ehrenhaft, 878
Isomaltose and Gentiobose, New Syntheses of, A Pictet and A Georg, 218
Isopulegone in the Natural State, The Existence of, V. Grignard and J Savard, 538
Isoquinoline and the Isoquinoline Reds, R T M Haines and Sir W. J Pope, 400
Isostasy. in Norway, W Heiskanen, 671; in the Southern Pacific, W Bowie, 246
Isotopes, The Line Spectra of, F. A Jenkins, 893
Italian Academy, Creation of an, 62, Alchemical Manuscripts, E J Holmyard, 544; Chemical Congress at Palermo, The, and the Cannizzaro Centenary, 840
Italy, pre-Roman, the Study of, 799

Japan, Chemical Society of, *Bulletin*, No 1, 495
Japanese Earthquake of 1923. Report on the, 493, The, Prof T Ogawa, 530
Javanese Architecture, 99
Jean Fernandez and Hawaii, The Flora of, Prof C. Skottsberg, Prof F L Stevens, 246
Jellies. The Structure of, P Thomas and Mlle Marie Sibi, 366; of Cellulose Acetate, The Elasticity of, in Relation to their Physical Structure and Chemical Equilibria, Dr H J Poole, 437
Jewish Calendar, The, W A Heidel, 735
Johannesburg 24-inch Refractor, The, Dr Van den Bos, 463
Joule-Thomson Effect in Air, J R Roebuck, 403
Journal: *de Biologie et de Médecine expérimentales.* No. 1, 281, *du Conseil* No 1, 740
Juvenile Crime, The Psychology of, Dr. M Ginsberg, 76

Kaiserliche Deutsche Akademie der Naturforscher zu Halle, Die, Dr F. A Bather elected a foreign member of, 317
Kame-moraines of the South of Scotland, The Great Re-advance and some later Stages of Retreat, J K. Charlesworth, 253
Kames and Drumlins in Scotland, Prof. J W Gregory, 670
Kangaroo Island, South Australia, The Fauna and Flora Reserve on, Prof F. Wood-Jones, 240
Kapteyn's Selected Areas, Parallax Survey of, O J Lee, 836
Karakoram Range Expedition, Discoveries by the, P. C. Visser, 167
Keith prize of the Royal Society of Edinburgh, The, awarded to Prof. H W. Turnbull, 699
Kelvin the Man, Mrs. Agnes Gardner King, 79
Kenya Colony, Archæology in, G. W B Huntingford, 497
Ketones, The Hydrogenation of, in the Presence of Pure and Impure Platinum Black, M. Faillebin, 290
Kew: Hand List of Coniferæ Third edition, 765; Royal Botanic Gardens · Exhibit of Plants of Economic Value, 97, post-cards of the, 495, re-imposition of an admission fee, 61
Khorasan, Dialect of, Rustic Poetry in the, W. Ivanow, 678
Kimmeridge Shale Oil, The Sulphur Compounds of, F. Challenger, J Haslam, R. J. Bramhall, and J. Walkden, 530

Kiwai: Papuans, Some Agricultural Rites of the, G. Landtman, [illegible]37; The, Dr A. C Haddon, 480
"Knock" in Internal Combustion Engines, 359
Krypton and Xenon, Request for, C. Cuthbertson, 699
Kumaon-Tibetan Frontier, Carabid Beetles from the, H. E. Andrews, 602
Kurus fought Pandavas, When, Hari Krishna Deb, 843
Kwakiutl, Ethnology of the, Contributions to the, Prof. F. Boas, 619

Labelling in Public Institutes for the Public, Miss L. E. Cheesman, 303
Lactic Bacillus, The Effects of the Intoxication of the, by Potassium Chloride at Different Temperatures, Mlle. Eudoxie Bachrach, 810
Laguerre's Series, On, E. Hille, 811
Lake Tana, Report of the Mission to, 1920–21, Dr. G. W. Grabham and R. P. Black, 806
Lakes, The 'Flowering' of, 768
Lamellibranchs, The Digestive Diverticula in the, Dr C. M. Yonge, 538
Land-Grant College Education, 1910–1920 Part III.. Agriculture, edited by W. C John, 175
Lap-chas of Sikhim, Folklore and Customs of the, C. de Beauvoir Stocks, 678
Lapland Wolf, The Coat of the, Prof. J. Cossar Ewart, 914
La Quina (Charente), The Aurignacian Station at, Dr. H. Martin, 429
Larix, the Staminate Cone of, Observations on the, J. Doyle, 742
Lauraceæ, On the Cuticles of some Fossil and Recent, Helena Bandulska, 609
Lavender Oil: from Irish-grown Plants, The Production of, Prof. J. Reilly, P. J. Drumm, and C. Boyle, 438; from the Irish Free State, Prof. J. Reilly, P. J. Drumm, and Prof C. Boyle, 871
Lead Pigment producing a Rustless Surface, A, Dr. A. V. Blom, 763
Leaia, Descriptions of New Species of, J Mitchell, 106
Leaves, Green, Yellow Leaves, and Red Leaves, The Chemical Characters of, H Colin and A. Grandsire, 254
Leeds University: the honorary degree of D.Sc. to be conferred on Prof. P. F. Kendall; Dr. F. M. Rowe elected to the chair of colour chemistry and dyeing, 741, B. A. McSwiney elected professor of physiology; Dr. R. D. Passey elected professor of experimental pathology and director of cancer research, 912
Left-handedness: a New Interpretation, B. S. Parson, 584
Legendre Function of the Second Kind, The Addition Theorem for the, T. M. McRobert, 35
Legion of Honour, Cross of an officer of the, conferment upon Sir Robert Hadfield of the, 61
Leitfossilien: ein Hilfsbuch zum Bestimmen von Versteinerungen bei geologischen Arbeiten in der Sammlung und im Felde Herausgegeben von G. Gurich. Vierte Lief: Leitfossilien der Trias. Wirbellose Tiere und Kalkalgen, Prof. C. Diener, 12
Leningrad, Academy of Sciences, election of new honorary members and correspondents, 355
Léopold, Ordre de, The, conferred on Sir J. C. Bose, 765
Lepidoptera, Induced Melanism in, Inheritance of, Dr. J. W. H Harrison and F C. Garrett, 740
Levulose, The Preparation of, R. F. Jackson, Clara G. Silsbee, and M. J. Proffit, 872
Levy, Louis Edward, medal of the Franklin Institute, The, awarded to Prof. E. G. Coker, 600
Library Co-operation Movement, Progress of the, 280
Lichtes, Wellenlangenmessungen des, im sichtbaren und unsichtbaren Spektralbereich, Prof P. Eversheim, 751
Life: and Evolution, an Introduction to Human Biology, Prof. S. J. Holmes, 779; Expectation of, Prof. Raymond Pearl, 634; Manifestations of, Prof. E. Rignano, 767; The Unity of, a Book of Nature Study for Parents and Teachers, H R Royston, 371
Light: Corpuscles, Light Waves and, Prof. G. N. Lewis, 236; Intermediate, Dr. R. A. Houstoun, 79; Quanta and Photo-electric Emission, Prof C. G. Barkla, 448; Quantum Theory, The, Dr C. D. Ellis, 895; The Convection of, by Moving Matter, C. L. R. E. Menges; The Writer of the Note, 121; The Diffraction of, by Spherical Obstacles, Prof. C. V Raman and K S. Krishnan, 878; Waves and Light Corpuscles, Prof. G. N. Lewis, 236; What is a Beam of, F P., 344
Lighting of Coal Mines, The, E. Farmer, 206
Lightning: Flash, The, N. E. Dorsey, 787; Globular, Black and White, E Mathias, 214; On, Dr G C Simpson, 503
Lilaeopsis, The Genus, a Study in Geographical Distribution, Dr. A. W. Hill, 774
Lindsaya linearis, and *L. microphylla*, Miss May M. Williams, 36
Linen Industry Research Association, Report of the, 598
Line Spectrum, A Rich, Dr. Marion Eppley, 768
Linnean Society, election of officers of the, 869
Linseed: and some other Oils, The Crystalline Bromides of, H. Toms, 809; Oil, On the Change of Refractive Index of, in the Process of Drying and its Effect on the Deterioration of Oil Paintings, Prof A. P. Laurie, 914
Liquid. Surfaces, Frictional Forces in, C. T. Chase, 724, Viscosity under Pressure, Prof. P. W. Bridgman, 737
Lithium, the Isotopes of, The Direct Determination of the Relative Proportion of, M. Morand, 538
Lithuania, Archæology and Natural History in, 432
Liverpool University: appointment in, 32; an honorary degree to be conferred on H. C Chadwick, 808
Livingstone College: celebration of commemoration day, 904; report of, 1924–25, 62
Lizards, Placentation in, Prof. L Harrison and Miss H C Weekes, 497
Loach, A Hermaphrodite, Sunder Lal Hora, 843
Locomotive Driving Wheel, On the Action of a, F. W. Carter, 842
Loculus of Archimedes, The, R D. Oldham, 337
Locust, Influence of Temperature on the, Prof. V. P. Pospelov, 635
Locusts, Genetics of, Nabours, 669
London: Hospital Freedom Research Fund, The, 352; Museum, Dr. R. E M. Wheeler appointed keeper, etc., of the, 462, Traffic, Sir Henry Maybury, 389; University: resignation by Prof A V Hill of the Jodrell chair of physiology, conferment of doctorates, 32; conferment of doctorates, 215; Prof. A Smithells, 331; The Petrie medal and fund; appointments, 362, appointments; conferment of doctorates, 399; the title of professor conferred on Dr. J. S. Edkins, 435; report of the departmental committee on, 468, the Bloomsbury site, 501; Prof L Dudley Stamp appointed Sir Ernest Cassel reader in economic geography, and R B. Forrester Cassel reader in foreign trade at the London School of Economics, 501, conferment of doctorates, 534; constitution of the, 541; proposed statutory commission for, 608; impending resignation of Prof. J. A Fleming; bequest by Sir John Rotton; conferment of doctorates, Dr T F Sibly appointed principal officer, 741; re-sale of the Bloomsbury site; Resolutions of Convocation, 772; Annual Report on, Sir Cooper Perry, 840; College, Report for 1924–25, 572
Longchain Compounds, On Imperfect Crystallisation in certain, Dr. A. Müller, 721
Lophius Piscatorius, Anatomy of the Ductless Glands and the Lymphatic System of, R. H. Burne, 217
Lopulco System of Powdered Fuel, Progress of, 282
Louisiana Coast westward from New Orleans, An Expedition to explore the, 732
Low Temperature Research Laboratory, A, for Fruit and Vegetables, 425
Lower Carboniferous Plants, Knowledge of, J. Walton, 878

Papaver somniferum L., Hybridisation of, in relation to the Morphine Content of the Opium, F. Cavara and A. Chistoni, 611
Paper Coal from Toula in Central Russia, The Structure of the Plant-cuticles in the, J. Walton, 810
Papuan Headhunters, Among: an Account of the Manners and Customs of the old Fly River Headhunters, E. B. Riley, 480
Paramagnetic Minerals, The Magnetic Rotatory Power of some, at very low Temperatures, Prof. H. K. Onnes, J. Becquerel, and W J de Haas, 35
Paramagnetism Independent of the Temperature, P. Weiss, 290
Paris Academy of Sciences, Prize Awards for 1925 of the, 138
Partridges, Colour Variations in, Dr W. and G. Bateson, 173
Passivity, Catalytic Action, and other Phenomena, Dr. A S. Russell, 47
Patent Office, Appointment of W. S. Jarratt as Comptroller of the, 352
Peace, International, The Universities and, 845
Peat: in the British Isles, 500, Types of, and their connection with Afforestation, A. C. Forbes, 500
Pegmatites, Paragenesis of, K. L. Landes, 431
de Peiresc, Sieur Nicolas Fabri, Dr. C. Hagberg Wright, 353
Peking to Lhasa, From: the narrative of Journeys in the Chinese Empire made by the late Brig.-Gen. George Pereira. Compiled by Sir Francis Younghusband, 480
Pendulum Observations, Dutch, in a Submarine with a New Apparatus, Dr. J. J. A Muller, 531
Penrose's Annual: the Process Year Book and Review of the Graphic Arts. Edited by W. Gamble Vol 28, 1926, 447
Period System, The, Chemical Bonds, and Crystal Structure, Prof. A. Sommerfeld, 793
Periodic Variations, Minute, The Determination of, J. Bartels, 437
Peripatus in England, Birth of, Prof. W. J. Dakin and Miss M. G. C Fordham, 858
Perkin Medal of the American Section of the Society for Chemical Industry, presentation of the, to Dr R. B. Moore, 169
Permalloy, Magnetic Properties of, O. E Buckley and L. W. McKeehan, 838
Permian Insects, Dr. R. J. Tillyard, 872
Perthshire Natural History Museum, Catalogue of Mollusca in the, H. Coates, 665
Peru: Geological Society of, the *Boletin* of the, 391; Pottery Styles and Periods in, A. L. Kroeber, 567
Pestology, the College of, Lt-Col. the Hon. Cuthbert James, 60
Petrol-fields, A Possible Origin of, A. F. Lindemann, 159
Petroleum: American, Supply and Demand, 38; Exploration, Micro-organisms in, The Stratigraphical Value of, H. B Milner, 558; in the Maracaibo Region, Venezuela, C. M. Hunter, 807; The Origin of, H. B. Milner, 897, The Winning of, Prof. A W. Nash, 545
Petrols, Analysis of, An extension of the Method of Critical Solubility Temperatures for the, M. Aubert and E. Aubrée, 471
Petromyzon, The Biology of, III, G. Cotronei, 471
Pflanzengewebe, Grundlinien zur Entwicklungsmechanik der, Dr. H. Pfeiffer, 151
Pflanzenphysiologie, Lehrbuch der, Prof. S. Kostytschew. Erster Band: Chemische Physiologie, 889
Pharmacognosy, Practical, T. E. Wallis, 585
Pharmaceutical Society, Opening of the New Pharmacological Laboratories of the, 903
Phenological Observations and Results in Russia, Prof. P. J. Schmidt, 119
Phenology, International, J. E Clark, 413; F. A. Bellamy; J. Edmund Clark, 658
Phillips, Peregrine, the Inventor of the Contact Process for Sulphuric Acid, Sir Ernest Cook, 419
Philosophy: Contemporary British, Personal Statements (Second Series), Prof. J. Ward, and others, 887
Phosgene, The Action of, upon Glucina, C Matignon and J. Cathala, 218
Phosphorous Trioxide: The Glow of, Christina Cruickshank Miller, 604; The Slow Oxidation of, Part 1, C. C. Miller, 181; Part 2, 878
Photocatalysis at Mercury Surfaces, H. S. Hirst, 252
Photo-electric: Cell, Applications of the, 25; Polarimetry, Dr. J. Kenyon, 304; Photometry, The Use of Arcs and other Fluctuating Sources in, B. Kurrelmeyer, 657
Photogrammetry, Perspective conditions of, Lieut.-Col. W. N. MacLeod, 106
Photographic: Lens Interferometer, A, 207; Measurements of Buildings or other Structures, The use of an Artificial Horizon in, T. F. Connolly, 519; Spectrophotometer for the Ultra-violet, A, A. Cotton and R. Descamps, 211; Spectro-polarimeter, A, for the Ultra-violet, A Cotton and R. Descamps, 254; Stellar Photometry, J. A. Parkhurst and Miss Farnsworth, 208; Surveying, General Principles of, Col. H. S. L. Winterbotham, 106

Photographing the Inner Surface of a Rifle Barrel, S. Nakámura, 247
Photometry, Illumination and, Standards in, P. Good, and others, 397; Ultra-violet, Drs G. M. B Dobson and D. N Harrison, 724
Photophoresis, H. S. Patterson and Prof R Whytlaw-Gray, 365
Photosynthesis: the Assimilation of Carbon by Green Plants, Prof. W Stiles, 647
Phototopography a Practical Manual of Photographic Surveying Methods, A. L Higgins, 889
Phyllody in the Primrose Flower, F R. Browning, 518
Physical: and Optical Societies' Exhibition, The, 101, Chemical and Action at Surfaces, Dr. E K. Rideal, 626, Society of London, election of officers, 427
Physics. Experimental, 261; Experiments in, A Laboratory Manual of, Prof L R Ingersoll, 261, Practical: Exercises in, Sir Arthur Schuster and Prof. C. H. Lees, Fifth edition, 512; for the use of Students of Natural Philosophy, Part 2, 261, Theoretical, Introduction to, Prof A Haas, Vol 2, Translated by T. Verschoyle, 687; The Relationship of, to Aeronautical Research, H. E. Wimperis, 860
Physik, Die Evolution des Geistes der, 1873–1923, Prof. A D. Chwolson Aus dem Russischen ubersetzt von Prof V R Bursian, 8; in graphischen Darstellungen, F. Auerbach. Zweite Auflage, 227
Physiologie der Sinne, Abhandlungen zur, aus dem physiologischen Institut zu Freiburg i. B, Herausgegeben von J von Kries Funftes Heft, 116
Physiology, Bainbridge and Menzies' Essentials of Fifth edition, edited and revised by Prof. C. Lovatt Evans, 372; for Clinicians and Students, 372, Human, Principles of, Prof E. H Starling. The chapter on the Sense Organs edited by Dr H. Hartridge. Fourth edition, 648; Recent Advances in, Prof C. Lovatt Evans, 375; The Integration of, 648
Physiques appliquées à la chimie, Les méthodes, Prof. J. Job, 717
Pig, Prenatal Death and Sex Ratio in the, Dr. F. A E. Crew, 35, 394
Pigments and Paints, The Application of the Microscope to the Examination of, C. A. Klein, 536
Pila, The Anatomy of, Dr B. Prashad, 173
Pilansberg (Transvaal), The Alkaline Rocks and Ring-intrusions of, Prof S J Shand, 364
Pilze, Vergleichende Morphologie der, E Gaumann, 820
Pinnotheres veterum, On Nocturnal Colour Change in the Pea-crab, D. Atkins, 415
Pionocypris vidua (O F Mull), On the Feeding Mechanism of, Dr H. G Cannon, 34
Pithecanthropus, Recent Studies of, Dr. J. H. M'Gregor, 357
Pituitary Gland, The Active Principles of the, 727
Pituitrin in Mammals, The Secretion of, as shown by Perfusion of the isolated Kidney of the Dog, E B. Verney, 502
Pit-Vipers, South American, 297
Place-names, Changes of, by the Soviet Government, 565
Plagioclase, The Dispersion of, K Chudoba, 143
Plain Speaking, Rev. T. R. R Stebbing, 779
Planarian Species new to Britain, A, Dr. Kathleen E Carpenter, H. Whitehead and E Percival, 556
Plane: Algebraic Curves, On the Higher Singularities of, Miss C A Scott, 742; Waves, The Relativity Theory of, O R. Baldwin and Prof. G B. Jeffery, 363
Planets: Minor, B Asplind, 802; The Temperatures of the, Dr E Schoenberg, 319, The Total Energy of the, M. Pierucci, 471
Plant: and Animal Improvement: a Textbook for Students of Agriculture, Prof E. Roberts, in consultation with Prof. E. Davenport, 583, as a Measure of the Habitat, The, J. F. V Philips, 736, Colonisation of the Sea-shore, Prof F. W. Oliver; Prof. Mangham, 635, Forms and their Evolution in South Africa, Prof J. W. Bews, 583, Gums, Enzyme in, Dr. G. J. Fowler and M. A. Malankdar, 64, Physiology, Contributions to, 320, The, as a Measure of the Habitat, J Phillips, 16
Plants: Economic, The Quest for, Dr A. W. Hill, 597; Ecotypes of, Prof. T D A Cockerell, 588; Flowering, The Classification of, Dr. A. B. Rendle Vol 2, Dicotyledons, 583; Plasts in, The Reversion of the, L. Emberger, 35, Records of, 636, Submerged, Respiration of, Influence of Temperature on the Intensity of, A. Hée, 201, The Comparative Chemistry of, XI, J Zellner and others, 143, The Physiology of the Principles of Food Production, Prof G J Peirce, 889; Transmission of Stimuli in, Prof. U Ricca, 654; Traumatropic Curvatures in, A. Beyer, 358
Platinum and Tungsten, The Concurrent Variations in the Thermionic and Photo-electric Emission from, with the State of the Surfaces of these Metals, T H Harrison, 503, Deposits in South Africa, Dr P. A Wagner, 530; Group Metals, Separation of, 321, in Southern Rhodesia, B. Lightfoot, 568, the Photo-electric Sensitivity of, Variations in, L. A. DuBridge, 743
Plotting from Air Photographs, Graphical Methods of, Lt.-Col L. N F I. King, 326
Poland, Fragment of a Horse Skull from Interglacial Deposits near Pulawy, E. Prawochenski and B. Kaczkowski, 914
Polar: Flight, Capt R. Amundsen's forthcoming, Col. U. Nobile, 461; Front, Greenland or, L C. W. Bonacina, 451, Prof W H. Hobbs, 232; Pastures, V. Stefansson, 280
Polarimetry, Photo-electric, Dr. J. Kenyon, 304
Polarised Light: on Bacterial Growth, Effects of, Prof S. S Bhatnagar and R. B. Lal, 302; Selective Action of, upon Starch Grains, Lord Rayleigh, Prof. W. Neilson Jones, 15
Pollen-grains, Winged, and Flowering Plants (Angiosperms), J. Parkin, 269
Polygons, Regular, The Construction of, 466
Polygonum cuspidatum, Application of the Biochemical Method of Research to the Glucosides undergoing Hydrolysis by Rhamnodiastase, to the Study of the Fresh Roots of, M Bridel and C Béguin, 291
Polyploidy: and Sex Chromosomes, Dr J. W. Heslop Harrison, 270, Prof. R R Gates, 234; Heterochromosomes and, Dr. J W. Heslop Harrison, 50
Pomo Indian, The Social Organisation of the, E W. Gifford, 803
Pomology, Systematic, Prof U P. Hedrick, 259
Pondoland, Ancient Coins from, J F. Schofield, 453
Population of the World, The Maximum possible, Sir George H Knibbs, 99
Porcelain Centrifugal Vessels in Chemical Analysis, Pincussen and Arinstein, 29
Porphyrin, On a new, H Munro Fox, 49
Port Development, Dr R S MacElwee, 262
Portuguese. East Africa, Cretaceous Gastropoda from, L. R Cox, 65, Oysters be produced on English Oyster Beds by Artificial Fertilisation in the Sea? Can, Dr J H Orton, 857
Potassium: and the Heat of the Earth, Dr A Holmes and Dr R W Lawson, 620, The Estimation of small quantities of, M Delaville and P Carlier, 610
Potato Diseases, Investigations on, P A. Murphy and R. McKay, 430
Prague, Charles IV. University, conferment of the degree of Doctor Rerum Naturalium on E B. Sanigar, 808
Prehistoric Discoveries at Prestatyn, F Gilbert Smith, 634
Pressure, The Variation of, from Month to Month in the Region of the British Isles, C E. P Brooks, 642
Prickly-pear in Australia, The Campaign against, A. P. Dodd, 625
Priestley medal of the American Chemical Society, The, Awarded to Prof. E F Smith, 699
Primitive Law and Order, Dr B. Malinowski, February 6, Suppt, 9
Primrose Flower, Phyllody in the, F. R. Browning, 518
Primula: the Calyx of, Modifications in, F. R Browning, 702, *vulgaris* Huds, On the Fertilisation of, E M, Jones, 106; Phyllody of the Corolla in, J. L Sager, 609
Prize Awards for 1925 of the Paris Academy of Sciences, 138
Progressive Thought and Traditional Doctrine, 221

Propylidene and Isoamylidene Acetone, The Preparation of, with Intermediate Production of the Corresponding Ketols, Pastureau and Mlle Zamenhof, 366
Protein Digestion by Enzymes, E. Waldschmidt-Leitz, 568
Protopterus and Lepidosiren, The Development of the Cranial Muscles of, F. H. Edgeworth, 914
Protozoa, Organisation in, Prof. G. N Calkins, 871
Protozoology, The History of, Prof F. J. Cole, 650
Pruning, The Lorette System of, Prof. L. Lorette Translated by W. R Dykes, 259
Prussian Universities and Technical Colleges, Statistics of, 399
Psyche: the Cult of Souls and Belief in Immortality among the Greeks, E Rohde Translated by W. B. Hillis, 889
Psychology: and Techno-psychology, International Association for Inauguration of the, 667, Applied, Prof J. McKeen Cattell, 534, its present Development and Outlook, Dr. N. N. Sengupta, 699; of Selecting Men, The, Prof. D. A. Laird; Miss W. Spielman, 444; to Social Hygiene, Contribution of, Prof C. Burt, 599
Public Health in Theory and Practice: an Historical Review, Dr. W H. Welch, 115
Punjab, Sedentary Games prevalent in the, A few Types of, Hem Chandra Das-Gupta, 679
Pyrometers: Recent Developments in Pyrometric Appliances and Methods for Calibrating Temperature-measuring Instruments; with Notes on Electric Furnaces, Dr. Ezer Griffiths, 617
Pyrometric Methods, 617
Pyroxenes, The Enstatite-Augite Series of, Dr. L. L. Fermor, 136; Dr. B. Asklund, 137

Quantum Mechanics: and a Preliminary Investigation of the Hydrogen Atom, P. A M Dirac, 324, The Elimination of the Nodes in; Relativity, with an Application to Compton Scattering, P. A. M Dirac, 842
Quartic Surfaces in Space of Four Dimensions, On a Set of, and a certain Involutory Transformation, H. G. Telling, 180
α Quartz, Structure of, R E Gibbs, 179
Quaternary Climates, J. C Jones, and others, 238
Queensland, Discovery of a Dinosaur in, H. A Longman, 838
Quetta, British Baluchistan, site near, selected for a new solar observation station, 425

RaB and RaC, The Period of Decay of, P. Bracelin, 253
Racial Purification, 257
Radiating Masses: The Law of Inertia for, Sir Joseph Larmor, 300; The Motion of, and the Effect of Radiation Pressure, Dr J. H. Jeans, 376
Radiation: arising from the Mutual Annihilation of Protons and Electrons, Profs. A. Ll. Hughes and G. E. M. Jauncey, 193; emitted by optically excited Zinc Vapour, J. G Winans, 181; from Electric Discharges through Gases, Sir J. J Thomson, 425; Intensities, Measurement of, by Photographic Methods, Dr. F. C. Toy, 83; Dr. R A. Houstoun, 159; I. O. Griffith, 344; Pressure, The Motion of Radiating Masses and the Effect of, Dr. J H. Jeans, 376; The Intermittent Theory of, Sir J. J. Thomson, 606, Prof E. T. Whittaker, 607; the Law of, Note on, Sir Oliver Lodge, 891
Radiations invisibles, La lumière et les, Prof. A. Bouartic, 853
Radio: Communication: and Imperial Development, Dr. W. H. Eccles, 659; Progress of Beam Stations for Short Wave, 62; Progress of, 131, Signals, Variations in, C. J. Jansky, 359, Stations, High-powered Transmitting, Phenomena observed in, G H. Farnes, 280, telegraphy, Transmission Formula for, L. W. Austin, 838; Telephony, Transatlantic, 386; -transmission of Photographs, 867; Wave Propagation, Dr. Hulburt, 872; Year-Book, The, 1926 (Fourth Year), a Book of Reference for all interested in Broadcast Receiving, 227
Radioactive Atoms, The Nucleus of, J. Thibaud, 65
Radioaktivnich Látek, Úvod do Chemie, Dr. A S. Russell. Translated by Prof. A Šimek, 44
Radium D and Radium E, Adsorption Experiments with, J P McHutchison, 363; Estimation, Obliquity Corrections in, I. Backhurst, 609
Raggi Ultravioletti, 698
Railway Electrification, H. Parodi, 353
Rain: Cotton in the Sudan, R. A. Wardle, 401; Gauges, Experiments in the Shielding of, C D Stewart, 33
Rainfall: of Dry Periods in Relation to Water-power Schemes, The, 176; of 1925, The, R. Corless, 206; Statistics over the British Isles, 1925, 168
Ramsay Memorial Fellowships: award of, 215; Report on the, 288
Rare Earth: and Alkali Metals, Double Sulphates of the, (iii.), F. Zambonini and G. Carobbi, 71, (iv.), F. Zambonini and G Carobbi, 181; (v.), F. Zambonini and S. Restaino, 643; Metals, The Isomorphism of the Molybdates of, with those of Calcium, Strontium, Barium, and Lead, F. Zambonini and R. G Levi, 71; (iv), 181
Rat: A New Nematode from the, Eloise B. Cram, 767; The Sexual Cycle of the, B. P. Wiesner, 539
Rats, Bones of, Determination of Moisture, Calcium, and Phosphorus in the, A L Bacharach, 470
Ray Society, election of officers, 427
Rays, Cosmic, C. S. Wright, 54
Reactions by Precipitation, The Use of Mixtures of Water and Alcohol in the Electrometric Study of, J. A Athanasiu, 439
Reading: University College, receipt of a Royal Charter conferring the status of a university, 468; The New University of, Principal W. M. Childs, 572
Reality: In Search of, I.: Organic Evolution, J. E. Williams, 779
Recinus communis, The Development of, in a Culture Medium rendered Radioactive by the Addition of Thorium-X, Averseng, Jaloustre, and Maurin, 611
Recoil Atoms, the Mobility of, A Photographic Method of determining, G. H Briggs, 34
Red: and Blue Colouring Matters of Flowers, Prof. R. Robinson, 278, Formations, The Colour of, G. E Dorsey, 703; Sea, Currents in the, Prof F. Vercelli, 603
Reef-encircled Islands, Subsidence Rate of, Prof. W. M. Davis, 575
Refraction, Low Errors of, The Significance and Detection of, O. Aves, 400
Regeneration Tissue, The Morphological Impotence of, P. Weiss, 143
Regional Scientific Work, 102
Regions of Compression, Dr. J W. Evans, 503
Rejuvenation, Sterility and, 560
Relativity: Doublets and Anomalous Zeeman Effect, A Possible Explanation of the, by means of a Magnetic Electron, F R Bichowsky and H. C. Urey, 575; More, 885; The ABC of, Hon. Bertrand Russell, 885; Theory, Tests of, Prof. A. S. Eve, 520; (A Correction), Prof. A. S. Eve, 766
Religion, Science and, 475
Reprints: References and Re-paging of, Dr. F. A. Bather, 516; E Heron-Allen, 517; Re-paging of, Dr. R. H. Rastall, 418
Reptiles, The Osteology of the, Prof. S. W. Williston. Arranged and edited by Prof. W. K. Gregory; Prof. J. Graham Kerr, 509
Research, The Taxation of, Profs. H. B. Baker and J Thorpe, 859, 894
Residual Ionisation in Closed Vessels, Dr R. W. Lawson, 235
Resistance Thermometers at Low Temperatures, A G. Loomis and J. E. Walters, 247
Resonance Radiation: Chemical Effects produced by, Prof. H. S. Taylor, A L Marshall, and J. R. Bates, 267; Dr. E. K. Rideal and H. S. Hirst, 449; The Quenching of, and the Breadths of Spectral Lines, R. W. Ditchburn, 34
Respiratory Function of the Blood, The Part I.: Lessons from High Altitudes, Prof. J Barcroft, 747
Reticularia Lycoperdon, The Life History and Cytology of, —One of the Mycetozoa, M. Wilson and Miss E. J. Cadman, 878

REVIEWS AND OUR BOOKSHELF.

Agriculture, Forestry, and Horticulture:

Bidwell (Dr. P. W.), and Prof. J. I. Falconer, History of Agriculture in the Northern United States, 1620–1860, 506
Bunyard (E. A.), A Handbook of Hardy Fruits more commonly grown in Great Britain. Stone and Bush Fruits, Nuts, etc., 259
Foster (L. F.), Principles and Practice of Farm Bookkeeping: a Text-Book for Agricultural Students, 548
Gunther (Dr. R. T.), The Herbal of Apuleius Barbarus, from the Early Twelfth-century Manuscript formerly in the Abbey of Bury St. Edmunds (MS. Bodley 130), 617
Hedrick (Prof. U. P.), Systematic Pomology, 259
Howell (J. P.), An Agricultural Atlas of England and Wales: Made on behalf of the Agricultural Economics Research Institute, University of Oxford, 408
Lorette (Prof. L.), translated by W. R. Dykes, The Lorette System of Pruning, 259
Marshall (Dr. F. H. A.), and J. Hammond, The Physiology of Animal Breeding, with special reference to the Problem of Fertility, 717
Murray (J. Alan), The Science of Soils and Manures. Third edition, 549
Roberts (Prof. E.), in consultation with Prof. E. Davenport, Plant and Animal Improvement: a Textbook for Students of Agriculture, 583
Rothamsted Experimental Station Library. Catalogue of the Printed Books on Agriculture published between 1471 and 1840, with Notes on the Authors by Mary S. Aslin, 751
Smythies (E. A.), India of To-day. Vol. VI.: India's Forest Wealth. Second edition, June 12, Suppt., 43

Anthropology and Archæology:

Best (E.), The Maori as he was: a Brief Account of Maori Life as it was in Pre-European Days, 42
Boas (Prof. F.), Contributions to the Ethnology of the Kwakiutl, 619
Budge (Sir E. A. Wallis), The Mummy: a Handbook of Egyptian Funerary Archæology. Second edition, 407
Delaporte (Prof. L.), translated by V. Gordon Childe, Mesopotamia: the Babylonian and Assyrian Civilization, 151
Gann (Dr. T.), Mystery Cities: Exploration and Adventure in Lubaantun, April 3, Suppt., 17
Glotz (Prof. G.), The Ægean Civilisation, 716
Hollingworth (E. J.), and M. M. O'Reilly, The Anglo-Saxon Cemetery at Girton College, Cambridge: a Report based on the MS. Notes of the Excavations made by the late F. J. H. Jenkinson, 619
Petrie (Sir W. Flinders), Ancient Egyptians, compiled and abstracted upon the plan organised by Herbert Spencer. (Descriptive Sociology: or Groups of Sociological Facts. Classified and arranged by Herbert Spencer. Division 1, No. 11), 578
Read (F. W.), Egyptian Religion and Ethics, 407
Spencer (Herbert), Descriptive Sociology: or Groups of Sociological Facts. Division 1, No. 11: Ancient Egyptians, compiled and abstracted upon the plan organised by Herbert Spencer, by Sir W. Flinders Petrie, 578
Verneau (Prof. R.), Les origines de l'humanité, April 3, Suppt., 17
Wheeler (Dr. R. E. M.), Prehistoric and Roman Wales, April 3, Suppt., 17
Wickwar (J. W.), Witchcraft and the Black Art: a Book dealing with the Psychology and Folklore of the Witches, 190

Biology:

Amaral (Dr. A. Do), A General Consideration of Snake Poisoning and Observations on Neotropical Pit-Vipers, 297
Angola et Rhodesia (1912–14). Mission Rohan-Chabot sous les auspices du Ministère de l'Instruction publique et de la Société de Géographie. Tome 4: Histoire naturelle. Fasc. 1: Mammifères, 114
Arber (Dr. Agnes), Monocotyledons: a Morphological Study, April 3, Suppt., 20
Balfour-Browne (F.), Concerning the Habits of Insects, April 3, Suppt., 19
Bathurst (Earl), The Breeding of Foxhounds, June 12, Suppt., 42
Berland (L.), Faune de France. 10: Hyménoptères vespiformes, I. (Sphegidæ, Pompilidæ, Scoliidæ, Sapygidæ, Mutillidæ), 511
Bews (Prof. J. W.), Plant Forms and their Evolution in South Africa, 583
Biologie, Ergebnisse der, Herausgegeben von K. v. Frisch, R. Goldschmidt, W. Ruhland, und H. Winterstein. Erster Band, 783
Biologischen Arbeitsmethoden, Handbuch der, Herausgegeben von Prof. E. Abderhalden. Lief. 173. Abt. 9: Teil 2, 1 Halfte, Heft 2, 513; Lief. 182. Abt. 9: Methoden zur Erforschung der Leistungen des tierischen Organismus, Teil 1, 2 Halfte, Heft 1. Spezielle Methoden. Tierhaltung und Tierzuchtung. Zuchtung von wirbellosen Tieren, 785
Blake (E. G.), Enemies of Timber: Dry Rot and the Death-Watch Beetle, in which the Origin and Life-History of the two worst Enemies of Timber are given, with a Description of the Damage they cause, and the Methods to be adopted for their Examination, 581
Boulenger (E. G.), The Aquarium Book, June 12, Suppt., 41
Bronn (Dr. H. G.), Klassen und Ordnungen des Tierreichs wissenschaftlich dargestellt in Wort und Bild. Sechster Band, Abt. 1: Pisces (Fische). Bearbeitet von Prof. M. Rauther. Lief. 39. Funfter Band: Arthropoda. Abt. 2: Myriapoda. Bearbeitet von Dr. K. W. Verhoeff. Lief. 100. Dritter Band: Mollusca (Weichtiere). Buch 2: Pulmonata. Bearbeitet von Dr. H. Simroth, fortgefuhrt von Dr. H. Hoffman. Lief. 147, 511
Browning (Prof. C. H.), Bacteriology, 79
Cole (Prof. F. J.), The History of Protozoology, 650
Crowder (W.), Dwellers of the Sea and Shore, 412
Cuénot (Prof. L.), L'Adaptation, 447
Daniel (R. J.), Animal Life in the Sea, April 3, Suppt., 19
Davidson (Dr. J.), A List of British Aphides (including Notes on their Synonymy, their recorded Distribution and Food Plants in Britain, and a Food-Plant Index), 512
Dewar (D.), Indian Bird Life: or, the Struggle for Existence of Birds in India, 851
Donne (T. E.), Red Deer Stalking in New Zealand, 512
Eames (Prof. A. J.), and Prof. L. H. MacDaniels, An Introduction to Plant Anatomy, April 3, Suppt., 21
Eugenics, Annals of. Vol. 1, parts 1 and 2. Edited by Karl Pearson, assisted by Ethel M. Elderton, 645
Fauré-Fremiet (Dr. E.), La cinétique du développement: multiplication cellulaire et croissance, 9
Fitzsimons (F. W.), The Monkey Folk of South Africa. Second edition, April 3, Suppt., 18
Fordham (Mahalah G. C.), Aphrodite aculeata, 375
Gamble (J. S.), Flora of the Presidency of Madras. Part 7, 785
Gäumann (E.), Vergleichende Morphologie der Pilze, 829
Haines (H. H.), The Botany of Bihar and Orissa: an Account of all the known Indigenous Plants of the Province and of the most Important or most commonly Cultivated Exotic Ones. 6 Parts, 225
Hammond (J.), Reproduction in the Rabbit. With Foreword and Chapter on the Formation of the Corpus Luteum by Dr. F. H. A. Marshall, June 12, Suppt., 42
Heilmann (G.), The Origin of Birds, 883
Herrick (Prof. G. W.), Manual of Injurious Insects, 888
Hirsch-Schweigger (Dr. E.), Zoologisches Worterbuch, April 3, Suppt., 19
Holmes (Prof. S. J.), Life and Evolution: an Introduction to General Biology, 779
Hutchinson (J.), The Families of Flowering Plants. I. Dicotyledons, 478

Hutton (Capt F W.), and J Drummond, The Animals of New Zealand: an Account of the Dominion's Air-breathing Vertebrates Fourth edition, 512
Ingram (C.), The Birds of the Riviera: being an Account of the Avifauna of the Côte d'Azur from the Esterel Mountains to the Italian Frontier, 785

Scientific Worthies.

XLIV.—ALBERT ABRAHAM MICHELSON.

THE co-operation of members of the English-speaking race is heartily welcome in many departments of human activity, some of them presumably more important even than the pursuit of science. But to us who are engaged in that study, the brilliant results obtained of late years in the United States, and the friendly co-operation existing between that country and the different parts of the British Empire, are a suitable subject of felicitation; and I am privileged to write an article in appreciation of the work of one of the most distinguished physicists in the world, the circumstances of whose normal life I understand to be as follows:

Albert Abraham Michelson was born in Strelno, Poland, on December 19, 1852. In 1854 his parents migrated to the United States. After emerging from High School in San Francisco, young Michelson was appointed to the Naval Academy, from which he graduated in 1873, and two years later became instructor in physics and chemistry under Admiral Sampson, continuing this work until 1879. After a year in the Nautical Almanac Office at Washington, Michelson, now an ensign, went abroad for further study at the Universities of Berlin and Heidelberg, and at the Collège de France and the École Polytechnique in Paris. Upon his return to the United States in 1883 he became professor of physics in the Case School of Applied Science, Cleveland, Ohio; whence, after six years, he was called to Clark University, where he remained as professor until 1892, when the University of Chicago opened its doors. Prof. Michelson went to this new institution as professor of physics and head of the department, a position which he still holds. In June 1925 he was honoured by being appointed to the first of the Distinguished Service Professorships made possible by the new development programme of the University.

It was while he was at Cleveland that Prof. Michelson collaborated with Prof. Morley in their joint experiment; and it may have been for the purpose of that experiment that he invented his particular form of interferometer, with the to-and-fro beams at right angles. Later, he applied it in Paris to the determination of the metre, with an estimated accuracy of about one part in two million.

During the World War, Prof. Michelson re-entered the Naval Service with the rank of Lieutenant-Commander, giving his entire time to seeking new devices for naval use, especially a range-finder, which became part of the U.S. Navy Equipment.

So recently as 1924 he undertook a very accurate determination of the velocity of light, using Mount Wilson and San Antonio, 22 miles apart, as the stations. It is believed that he intends to continue this with a base-line 90 miles long, so as to obtain this great fundamental constant with extreme accuracy.

A Nobel Prize was awarded to Prof. Michelson in 1907, the first American to get one for science; and the Copley Medal, the most distinguished honour of the Royal Society of London, was awarded him in the same year.

The gold medal of the Royal Astronomical Society was presented to Prof. Michelson on February 9, 1923; and the compact exposition of the reasons for that award by the president, Prof. Eddington, on that occasion will be found in NATURE, vol. 111, p. 240.

As an expounder of scientific progress it is interesting to read Michelson's address given as retiring president of the American Association for the Advancement of Science, which fortunately has been reproduced in NATURE of January 11, 1912 (vol. 88, p. 362). It covers a lot of ground and the work of many people; and one characteristic of it is the slight emphasis on his own name in connexion with his own work.

Let us see if we can obtain some idea, not indeed of the whole scope of his work, but of some of the salient and outstanding features of it.

Michelson has touched on many departments of physics, but in optics, the highest optics, he excels. In this subject he can be regarded as the most fertile and brilliant disciple of the late Lord Rayleigh, for his inventions are based on a thorough assimilation of the principles of diffraction, interference, and resolving power; and his great practical achievements are the outcome of this knowledge. In this appreciation a reminder of some of the salient features of that work must be appropriate. But his papers cover far more than general principles; they enter into minute details, as is always necessary when theory has to be translated into experiment and instrumental construction. He has been happy in having at his command the possibilities of equipment provided by enlightened citizens of the United States of America; he has been aided by the singular skill of some instrument-makers both in the States and in Great Britain; but without a thorough grasp of theory his ingenious designs would have been impossible.

Michelson seems to have a special instinct for all phenomena connected with the interference of light, with a taste for exact measurement surpassed by none in this particular region. The interferometer with which he began became in his hands much more than an interferometer. He applied it to the determination of the standard metre in terms of the wave-length of light, with exact results which will enable remote posterity millions of years hence to reconstruct, if they want to, the standard measures in vogue at this day. He applied it also to analyse the complex structure of spectrum lines, and with remarkable completeness to determine the shape and size of invisible objects, such as to ordinary vision, however much aided by telescopic power, will probably remain mere points of light. NATURE is read by many other than physicists, and a rough general idea of how these things were accomplished may be welcomed

The kind of interferometer dependent on the use of a semi-transparent plate was begun so long ago as 1859 by Fizeau, who thus split a beam of light into two halves, and with the aid of auxiliary silvered mirrors sent the beams round a circuit along identical paths in opposite directions, so as to become reunited at their point of separation. Thus, by alternate concurrences and oppositions of phase, the illumination was redistributed into bands of remarkable brilliance, which bands would shift in position if any cause accelerated one of the half beams and retarded the other.

Michelson modified this arrangement by altering the angle of the auxiliary mirrors, and setting them perpendicular to the light, so as not to send the two beams round a contour, but to reflect each back upon itself. Each half-beam then makes a to-and-fro journey along its own path, the interference fringes being produced, as before, when the beams reunite at their point of initial separation at the end of their independent journeys. The accidents which can happen to such separated beams are of a different character from those operative in the Fizeau arrangement, and it becomes a different instrument.

If we begin with the two paths equal; noting the position of the fringes by a micrometric device, and then gradually lengthen one of the paths by making its perpendicular mirror retreat, the bands will shift so as to interchange bright for dark when the mirror has retreated a quarter-wave length—which, of course, is an exceedingly small amount. If, by a screw motion, we make the mirror gradually move backwards, an eye at the micrometer will see the bands sailing or floating past, in such a way that their passage can be counted; and we can thereby determine how many wave-lengths the mirror has retreated. We might thus cautiously move it back a centimetre, or even a decimetre, and might then, by ingenious devices and different standard gauges of length, gradually extend the range virtually to as much as a metre: thus counting with extreme precision, and to a small fraction, the number of waves in that length,—using, of course, very homogeneous light, such as is given by a line in the spectrum of cadmium or mercury, or other monatomic substance emitting a simple kind of light.

Now suppose the source of light is not simple: suppose instead of being a single line, it is a double one. Then what will be the effect? The wave-length of the two lines is slightly different. With some adjustments the interference bands may agree in position, so that they are clear and plainly visible: with other adjustments the bright parts of one set may overlap or be superposed upon the dark parts of the other; thus restoring a uniform illumination, and making the bands disappear. A further adjustment in the same direction will cause them to reappear again, and so on periodically. By studying these variations of visibility, and plotting a curve to represent them, after the manner of Rayleigh (see his "Investigations in Optics," *Phil. Mag.*, 1879 and 1880, or Paper Number 62, in vol. i. of his "Collected Scientific Papers"), the nature of the source can be specified with precision, and the relative intensity of the components of the double or multiple source ascertained.

Perhaps the easiest way of getting a general idea of the process is to employ a very simple interference instrument, such as two parallel slits in a card, mounted in a tube like a taper-holder, to which the eye is applied, and then look at a fine line of light like a luminous hair. Interference bands will be seen, caused by the meeting and overlapping of the beams which have come through the two slits. (Lord Rayleigh describes such an easily-made and popular instrument in vol. iv. of the "Collected Papers," p. 76.) Now imagine the source of light shifted parallel to itself, through a distance which when multiplied by a reducing fraction (the ratio of the distance between the slits to their distance from the source) will equal half a wave-length of light. The bands will now look the same as before, but the bright bands will be in the dark bands' places; thus indicating the amount which corresponds to a half wave-length shift. Next, imagine a precisely similar source placed in the original position, and look at the two together. Each will give its own set of bands, but no bands will be visible, because the bright parts of the one will blot out the dark parts of the other. Separate the two sources a little more, or bring them a little nearer together, and in either case the bands will reappear.

We may next proceed to consider what happens when, instead of the two simple sources of light, a square or oblong patch of light is looked at, filling up the space between the two positions. The thing is now becoming a little more complicated, and a numerical factor will have to be introduced depending on the shape of the source of light. It need not be an oblong; it might be a triangular patch, or a circular disc, or any other simple shape. Michelson made a serious study of what would happen for all manner of luminous apertures, and found that a numerical factor could be introduced appropriate to each simple shape, and drew the visibility curve to be expected under the various conditions. This paper will be found in the *Phil. Mag.* for April 1891; and in September 1892 his later paper applied the curves to determine the peculiarities of spectrum lines employed as the source of light.

Before that, however, Michelson had realised that on Rayleigh's principles the resolving power of a telescope could be indefinitely increased by using it to form, not an ordinary image of an object, but the diffraction or interference pattern of such an object.

An early paper by Lord Rayleigh on "The Resolving Power of Spectroscopes," in which the main theory is given, is in the *Phil. Mag.* for March 1874. (See also vol. i. of "Collected Papers," pp. 316, 420, and 424.)

Early in the century that remarkable genius, Thomas Young, had devised what he called an "eriometer" for measuring the size even of very minute granules by their diffraction pattern,—for example, the rings of the halo formed by such a substance as lycopodium. Rayleigh suggested an extension of this method in his "Encyclopædia Britannica" article, "Wave Theory," where he gave the theory of different apertures, and refers to previous workers in France and elsewhere. (Paper Number 148 in vol. iii. of "Collected Papers.")

Michelson pursued the subject into great detail; and in a magnificent paper in the *Phil. Mag.* of July 1890 he suggested the application of interference methods to astronomy. He knew well that the resolving power of a telescope depended on the diameter of its aperture, and that the formation of an image was essentially an interference phenomenon; the minuteness of a point image, and therefore the clearness of definition, depending on the size of the object-glass. But he pointed out that if the aperture was limited to slits at opposite edges—so that no actual image anything like the object would be formed, but only the interference bands which the beams from the two slits could produce—a study of those bands would enable us to infer about the source of light very much more than we could get by looking at its image. For example, suppose it was a close double star, and suppose the slits over the object-glass were movable, so that they could be approached nearer together, or separated the whole distance of the aperture apart. A gradual separation of the slits would now cause the fringes to go through periods of visibility and invisibility; and the first disappearance of the fringes would tell us that the distance apart of the two components of the star (multiplied by the distance between the slits and divided by the distance of the star) would equal half a wave-length of light. The two components might be far too near together ever to be seen separately, and yet we could infer that the star was a double one; and by further attention to the visibility curve we could infer the relative brightness of the two components and their position relative to our line of sight.

Furthermore, if, instead of looking at a star, we turned the slit-provided telescope on a planet with a disc too small for ordinary measurement, the size of that disc could be estimated from the behaviour of the interference fringes produced by its light in a suitable interferometer, or by the telescope converted into one.

Michelson begins this 1890 paper thus:

> "In a recent paper on 'Measurement by Light-waves' it was shown that the limitation of the effective portions of an objective to the extreme ends of a diameter converted the instrument into a refractometer; and although definition and resolution are thereby sacrificed, the accuracy may be increased ten to fifty fold.
>
> "The simplest way of effecting this in the case of a telescope is to provide the cap of the objective with two slits adjustable in width and distance apart. If such a combination be focussed on a star, then, instead of an image of the star, there will be a series of coloured interference-bands with white centre, the bands being arranged at equal distances apart and parallel to the two slits The position of the central white fringe can be marked from ten to fifty times as accurately as can the centre of the telescopic image of the star.
>
> "One of the most promising applications of the method is the measurement of the angular magnitudes of small sources of light."

Michelson further realises, even at this early date, that by this method the virtual aperture of a telescope may be immensely increased by supplementing it by a pair of receiving mirrors beyond the object-glass, catching the light at 45°, and sending it towards the object-glass, where it is caught by two other mirrors, and sent down towards the eye. The interference-fringes now formed will be as if the two slits were separated by the whole distance of the outer mirrors apart. He then says that, by means of a right-and-left-hand screw, the mirrors are to be separated until the fringes disappear; when the angular diameter of the planet, if its disc is circular and uniformly illuminated, will be the ratio of a wave-length of light to the distance between the mirrors, multiplied by the numerical factor 1·22. This factor, it is interesting to note, was obtained by Sir G. B. Airy so long ago as 1834 (*Camb. Phil. Trans.*) as the appropriate number for a uniformly illuminated disc, when he was considering the resolving power of a telescope as dependent on the diameter of its object-glass. (See also Rayleigh, vol. i. p. 416.)

Michelson then goes on:

> "The chief object of the method proposed is the measurement of the apparent size of minute telescopic objects, such as planetoids, satellites, and possibly star discs, and also double stars too close to be resolved in the most powerful telescope . . . It would appear that a one-inch glass may be made to do the work now required of a ten-inch."

In view of the extraordinary and sensational interest which has been aroused by the recent application of this method by Michelson himself, with the aid of collaborators at Mount Wilson Observatory, Pasadena, California, and with the hundred-inch telescope established there, it may be interesting to quote here part of the conclusion of this paper of Michelson's of date 1890:

> "(1) Interference phenomena produced under appropriate conditions from light emanating from a source of finite magnitude become indistinct as the size increases, finally vanishing when the angle subtended by the source is equal to the smallest angle which an equivalent telescope can resolve, multiplied by a constant factor depending on the shape and distribution of light in the source and on the order of the disappearance.
>
> "(2) The vanishing of the fringes can ordinarily be determined with such accuracy that single readings give results from fifty to one hundred times as accurate as can be obtained with a telescope of equal aperture."

Then, after a few more clauses, comes this remarkable anticipation:

> "If among the nearer fixed stars there is any as large as our sun, it would subtend an angle of about one hundredth of a second of arc; and the corresponding distance required to observe this small angle is ten metres, a distance which, while utterly out of question as regards the diameter of a telescope-objective, is still perfectly feasible with a refractometer. There is, however, no inherent improbability of stars presenting a much larger angle than this; and the possibility of gaining some positive knowledge of the real size of these distant luminaries would more than repay the time, care, and patience which it would be necessary to bestow on such a work."

There seemed little hope at that time, and certainly no reasoned expectation, that any stars, except perhaps some of the very nearest, could have discs big enough for perception and measurement even by this virtual telescope of thirty feet aperture. But in the course of the quarter of the present century through which we have lived, mathematical astronomers have been busy. When the history of recent stellar astronomy comes to be written, some living names such as H. N Russell, Shapley, Eddington, and Jeans will shine as stars of the first magnitude. The possibility of giant stars—so named by Hertzsprung—has come above our mental horizon; and Eddington made the notable prediction that a star like Betelgeuse must be in a highly rarefied state at a tremendously high temperature, and that it would be swollen out by the pressure of light to a size almost comparable with the dimensions of a solar system, although it could not contain very much more matter than, say, two or five times our sun. His argument, in brief, is that the spectrum of a young red star like Betelgeuse shows that it cannot be radiating furiously. Why then is it so conspicuous an object to our vision? It can only be because it is of enormous size, its density perhaps a thousand times less than atmospheric air. By utilisation of the data available in the light of his theory of stellar constitution, Eddington made an estimate of the diameter of the star.

So with great skill Michelson and his collaborators got the interferometer to work. After many preliminary adjustments, on December 13, 1920, Dr. F. G. Pease at Mount Wilson, with Michelson's apparatus, measured the diameter of a star for the first time, using Betelgeuse for the purpose. The interference-fringes formed by the star were observed, the object mirrors were gradually separated, and it must have been a joyful moment when, as they grew farther and farther and farther apart, the fringes at the eye end became less distinct and ultimately disappeared. The distance apart of the mirrors now, multiplied by the proper fraction, gave the angular dimensions of the star—a thing which had never before been observed in the history of the world. An estimate of the star's distance gave its actual diameter, and confirmed Eddington's prediction!

Other stars have since been measured, and the giant stars well deserve their name. Moreover, an instrument has been put in the hands of posterity to the power of which we can scarcely set a limit in investigating utterly invisible details, both about the heavenly bodies and about atoms, by the new and powerful method of analysing the radiation which they emit.

The form of instrument adapted to the heavens is, however, not applicable to the atoms The spectrum of atomic radiation is formed by a grating; and Rayleigh showed (see "Collected Papers," page 427, vol. i) that the power of a prism spectroscope is expressed approximately by the number of centimetres of available thickness of glass, which is one form of saying that, to get high definition or separating power, we must use interference depending on a great number of wave-lengths retardation. The resolving power of a grating depends on its total aperture, which must always be limited to inches, since accuracy of ruling over the whole breadth is essential; but one can have retardation gratings, where the interference is caused, not merely by extra distance due to angular slope of path, but by the retarding effect of a dense substance, such as gelatine or something transparent, instead of by the successive obliterations or dark spaces of the grating. There would seem to be no particular advantage in that; but Michelson perceived that the retardation principle might be employed so as to make a grating which combined with its own effect the resolving power of a prism. A slab of glass a centimetre or more thick might be used to give the necessary lag in phase of many thousand wave-lengths, and thereby secure a definition and resolving power unthought of before.

So Michelson designed the Echelon spectroscope, consisting of thick slabs of glass, each protruding a millimetre or so beyond the other—a staircase spectroscope When he brought this out in 1898 in the *Astrophysical Journal*, vol. 8, p. 37 (see also *Am. J. Sci.* and *Camb. Phil. Trans.* for 1898–99), it seemed as if such an instrument could scarcely be constructed, or, if it were constructed, that the number of slabs must be very few. But I understand that the skill of Messrs. Adam Hilger has sufficed to construct an Echelon with so many as fifty slabs; and this, or some similar Echelon, is now a regular instrument in the examination of the minute structure of spectrum lines. Naturally it cannot cover a great range of the spectrum; it has to be fed with light of a nearly definite refrangibility, and then it analyses the light, as a high-power microscope analyses a small range of visible structure.

The striking thing about all these instruments is that they give us, by inference, information about the invisible; and further developments are to be expected. For example, in connexion with stellar variation Prof. Shapley had proposed a theory of periodic pulsation, which would enable a single star to vary without an eclipsing companion; and this hypothesis was taken up by Eddington for the case of the Cepheid variables.

Subsequent repetition of the Mount Wilson interferometer-measurements on Betelgeuse, after an interval, seems to show that variations in diameter actually occur; and probably by this time much more information has been obtained than can here be summarised. But it illustrates the power of the instrument to confirm the indications of theory.

Before leaving this part of the subject it may be interesting to refer physicists to Paper 199 in vol. iv. of Rayleigh's "Collected Papers," also in *Phil. Mag.* for November 1892, in the form of a letter from Lord Rayleigh to Prof. Michelson about the interference bands of nearly homogeneous light.

I will only add further that Michelson has applied his instrument to examination of the Zeeman phenomenon, with inferences about the multiple character of many of the lines, as recorded in his paper on "Radiation in a Magnetic Field" (*Phil. Mag.* for July 1897 and April 1898).

References to Michelson's earlier papers on this subject are:

A general theory of interference-fringes in a refractometer, in *Phil. Mag.* for April 1882; a mathematical paper on the visibility of interference-fringes in the focus of a telescope, in *Phil. Mag.* for March 1891; on the application of interference methods to spectroscopic measurement, in *Phil. Mag.* for September 1892.

Now I find that I have omitted all reference to what is the popularly best-known work of Michelson, the application of his interferometer to determine if possible the motion of the earth through the ether. The speed expected was of the order one-ten-thousandth of the velocity of light; but since the journey of the light in the instrument is a to-and-fro journey—one half-beam going as nearly as possible with and against the hypothetical stream of ether, while the other half-beam goes at right angles to that direction—the amount to be measured was not one-ten-thousandth but the square of that quantity; that is to say, the observer had to measure one part in a hundred million—no easy matter. The apparatus has been so often described, and the theory so often given, that there is no need to say much about it. The interferometer was mounted on a stone slab floating in mercury, and the whole observation conducted with great care. The result was zero; and that zero was used afterwards as the corner-stone of the great and beautiful edifice of relativity.

That so extensive a structure should have been initiated by a zero result is philosophically curious, and shows great faith in the trustworthiness of the experimenters, Michelson and Morley. I am told that Morley, before he died, was rather overawed by the consequences deduced from that experiment, and was anxious that it should be repeated with still greater care, and under many conditions, some of which were indicated in their early paper (*Phil. Mag.*, December 1887), entitled "On the Relative Motion of the Earth and the Luminiferous Æther," by Albert A. Michelson and Edward W. Morley. For even then they suggested, on page 459, that perhaps at moderate distances above the level of the sea, or at the top of an isolated mountain peak, the relative motion might be perceptible.

Such repetition has, as we know, lately been attempted, with results which at present seem too unlikely to be credited; but as Prof. Miller's experiments are *sub judice*, I will say no more about them. I know that Michelson agrees with me (or did in 1920) that there was nothing in the original Michelson-Morley zero result to justify a denial of the existence of the ether; nor is a positive result necessary to re-establish it. The theory of relativity (so called) has led to a search for *absolute* conditions, independent of accidents of motion, the same for all observers; and this search for the absolute will continue, being justified by its brilliant success, quite apart from the corner-stone which is still part of the structure. On the whole, the theory rather tends to strengthen our philosophic conviction of the ether as an integral and absolute ingredient in the universe, although, for purposes of calculation and attainment of results, it—like many other things—can be safely ignored.

I append references to such papers as were published in the *Phil. Mag.* on other subjects, for the convenience of any who would like to look at them:

"Note on an Air-Thermometer" (September 1882); "A Method for Determining the Rate of Tuning-Forks" (February 1883); "On the Relative Motion of the Earth and the Luminiferous Æther"—the first Michelson and Morley paper (December 1887); "On a Method of making the Wave-length of Sodium Light the Actual and Practical Standard of Length" (December 1887); "A New Harmonic Analyser"—Michelson and S. W. Stratton (January 1898); "The Velocity of Light" (March 1902); "The Relative Motion of Earth and Æther" (December 1904); a short mathematical paper on "Diffraction" (April 1905); "On Metallic Colouring in Birds and Insects" (April 1911).

OLIVER LODGE.

Discovery and Dialectics.

Science and Scientists in the Nineteenth Century. By the Rev. Robert H. Murray. Pp. xvii + 450. (London: The Sheldon Press; New York and Toronto: The Macmillan Co., 1925.) 12*s.* 6*d.* net.

DR. MURRAY, who is rector of Broughton and is distinguished as a historical writer, says: "In a sense my book forms an assault upon science, or to put it more correctly, upon the preconceptions that lie at its base far more than most F.R.S.s are aware." It is therefore permissible that a review of it in this journal should be, in a sense, a reply; for the book is very well written, it is interesting to read, and its data are culled from a wide range of the annals of men of science themselves; hence what one must call its misconceptions are likely to impress themselves upon a fairly wide public. On the other hand, there is a great deal in it from which scientific readers cannot fail to draw a very salutary lesson.

The virtue of the book lies in the emphatic warning, well hammered home by numberless examples, against pooh-poohing new ideas. The treatments of Jenner, J. Y. Simpson, Lyell, Joule, Darwin, Pasteur, and Lister by their contemporaries, together with less familiar and more briefly handled cases, are adduced in evidence of the futility of—may one coin a word?—Pooh-poomposity and the shut mind. It is a most valuable sermon on personal faults. Dr. Murray deplores the spending of time and energy which is exacted from discoverers by their need to silence hostile criticism, criticism which has turned out to be incorrect in the end, and has sometimes been rancorously expressed. No one defends personal rancour, whether it is *pro* or *contra*; "a man may be a champion for truth without being an enemy to civility"; and the same holds concerning cocksure affirmations and denials out-of-hand Whilst a lay listener often mistakes philosophic emphasis for personal antagonism when it is nothing of the kind, it remains perfectly true that there are little minds and ignoble minds among men of science as everywhere else, and there always will be. Moreover, no man of science, not even the greatest, has more than a short period in his life during which he is so free from human vanities that his discoveries are faultless and his opinions just.

To Dr. Murray, as a student and a curator of human nature, it has evidently been a disappointment to find, from his reading, that these things are so; but he has allowed them so to prey upon his mind, that he draws conclusions about science itself which are much too cheerless. For Dr. Murray, an admirer of great investigators, makes far too little of the real part which doubt plays in science. Even a great investigator is liable to be affected by the Idols of the Tribe and of the Cave, and when his admirers cavil at adverse conservatism, they are guilty of a worse heresy than are those whom they blame. Although the author does not omit to make mention of this, the tenor of the whole book is undoubtedly to cause it to be ignored by the reader. Scepticism is the great promoter of intellectual progress; and if every plausible idea had received general approval at its birth, or even general tolerance, the effect would have been chaotic—as, indeed, is indicated by the passage from Thucydides which Dr. Murray rather inconsistently quotes as the text of his book. No discovery is actual until it has been widely put to the test, for no discoverer ever sees all round his problem; and the result—one had almost said, the purpose—of opposition is to provoke the originator to make his claim good and better, by more observation. The onus of proof is on the discoverer: he is held guilty of misstatement unless he can clearly show the contrary; and in this ruthless but reverent safeguarding of truth lies the strength of the scientific method, not (as our author appears to think) its shame. Dr. Murray actually makes it a complaint that the man of science is "a dour deevil to convince"; of course he is, and if he had not been, there would have been no science; and the whole dour generation of them must be convinced before the new thing can become the true thing.

There are several matters wherein the author's vivacious biographical accounts might easily lead to a wrong impression. Jenner's opponents were mostly medical practitioners, not men of science; also, though Jenner was proved right about vaccination in the end, he had given a handle to critics, at the time when he had only a *prima facie* case, by having made rash inferences in other fields of study. Again, J. Y. Simpson's opponents were not men of science, they were surgeons; and they contested anæsthesia on ethical rather than on logical grounds, for while he urged that pain is wrong, they thought it natural and salutary. Not dissimilar remarks apply to Lister and antisepsis. As to Lyell in geology, Dr. Murray himself admits that "it was part of the good fortune of Sir Charles Lyell that he had suffered much from opposition." Concerning a problem studied by Darwin which had, unknown to him, been investigated before, is it ever true that a scientific research has been "done once for all"? On Joule and the conservation of energy, to say that Kelvin was "blinded by preconceived notions" is surely a little disrespectful to the vast knowledge of massed facts which is dismissed as "preconceived notions"? Was one research, by one man, to be allowed to change the face of all that Kelvin then knew? More experiments were what he asked for.

The important point that is missed by Dr. Murray, in common with most laymen, is that a research or an idea which can be achieved by one man alone has no standing as a truth in science. We are not as trustful of our own powers as that. When enough people have arrived at the same point, when the new thing has become a statistical experience and no longer an individual experience, then only is it authentic. This is an integral part, it would seem, of the canons of modern scientific proof. The process is like cupellation: the button of rich metal is purged of its dross in the fire of scepticism, and the golden bead of truth remains. Looking back, we see that a proved scientific truth is, in fact, something rather less than the greatest common factor of the current scientific beliefs on the question; it is to be found midway between those who believe too quickly and those who believe too slowly; and inevitably in due time it prevails, and it begets fresh truths. The business is certainly cumbrous and almost painfully slow—especially to those who cannot take part in it—because so many of us, being human, are as stupid as any of our lay brothers. But the process seems nevertheless to "get there" far more rapidly and more surely than does any other mode of inquiry.

Dr. Murray uncovers without concealment the axe which he has to grind. "One main purpose," he says, "in writing this book has been to prove that there are just as many preconceived notions in science as there are in theology"; and later he adds that his book stands or falls largely by this thesis He gives us, however, only one side of his equation, for we are not given the corresponding washing of the theologians' linen; and it strikes the unsophisticated scientific reader as a very cynical and despairing warrant for his line of argument when the author says: "In logic two blacks do not make a white, but in life they sometimes do." Apart from these merely dialectic comments, there remains one cardinal error, which vitiates the whole thesis: namely, to decry what lies at the base of science simply because its students are apt to go outside the scientific method. One might as well argue: "Some plumbers are socialists; I do not believe in Socialism, therefore a system of sanitation must be a bad thing." Science is the discovery of things, not a society of persons

The layman who reads this book would probably be led to fall into the same pit as its author, confusing investigators with what they help to discover; and the book is thus a poor guide for him. To scientific readers it forms a powerful sermon on good manners; it is a large collection of interesting personalia; and it can be recommended accordingly. IRVINE MASSON.

IF the output of the publishing press is a valid criterion, there is as yet no abatement of the wave of popular interest in physical and, in particular, in electrical science. Electricity is very much in the air at present. Schemes of electrification on a gigantic scale are advocated in Parliament and in the press. Above all, "wireless" receivers with their inductances and capacities, their metres and wave-lengths, and their valves, which brightly or dully glowing make the set not infrequently more pleasant to watch than to listen to, have brought the mysteries of electrical science on to the domestic hearth. It is not surprising that there are a considerable number of people who would like to know, if it can be managed without too much mental labour on their part, what electricity is and how it works. That such a demand really exists is proved by the statement of one of the authors of the volumes enumerated above, that he has been induced to produce the present volume by the hearty welcome to a former book on similar lines.

The demand is not an easy one to satisfy. The book must be cheap (there seems to be some unanimity among publishers that its price should be 2s. 6d.), for the desire to know is not one of those imperious passions which must be satisfied at any price. It must not require much from the reader in the way of concentration, or active thought. It must be attractively written and well illustrated, with photographs rather than diagrams, for diagrams are cold and repellent to all except the real enthusiast. In addition, the author will, in order to satisfy his own conscience, wish the book to convey some genuine knowledge to the reader, and to produce in his mind impressions which are not too unlike the actual facts. It is, of course, this last self-imposed condition which makes the writing of these books so difficult.

(1) Of the first three books on the list above, we think that "Electricity and the Structure of Matter" by Mr. Southerns is the most successful. Mr. Southerns has selected his material well, and shows, in his treatment of it, a light and deft touch. He possesses a fine sense of showmanship, which in the illustration where the author's pen pauses a moment to be X-rayed, rises almost to genius. He will probably find, however, that the X-ray installation figured in the frontispiece will work more satisfactorily if he connects in the condenser The book is most attractively illustrated and produced, and can be recommended warmly to any reader in search of a pleasant and not too profound account of modern electrical science.

(2) In comparison "The Story of Electricity" by W. F. F. Shearcroft is dull, and in spite of its dullness is distinctly less informative than the preceding volume. To attempt to deal with relativity in five small pages, and with the quantum theory in three, is asking for trouble. With the author's obvious desire to illustrate the nature and methods of scientific progress by a history of one of the sciences we have every sympathy. An excellent book might be written on these lines. It is not, however, a thesis which can be adequately developed in 62 pages of text.

(3) "Readable School Electricity" stands on a somewhat different footing from the two volumes already noticed, as it proclaims itself as being specifically a school book, one of the newer type based on the thesis that the object of a school book should be to stimulate the interest of the beginner, in the hope that, when his interest is stimulated, he will himself demand to be taught the grammar of the subject, so necessary to any true knowledge, but at the same time inevitably so dull. This is a thesis on which school masters and university teachers are apt to hold divergent views. The author of the present volume is not an extreme supporter of the thesis, and though the book deals mainly with applications of electricity, it is by no means entirely superficial, and there are scholarly touches which are most welcome in a school book on science.

(4) and (5) If any justification is possible for including in one and the same notice the volumes we have just dealt with and the two that remain for review, it must be that whereas the former represent a fair average of what popular science is, and perhaps must be at the present time, the latter are bright and shining examples of what it may become when a true interest in science for its own sake, and a real appreciation of its aims and discoveries, have become more general than they are as yet. The fact that Dr. Millikan's classic "The Electron," after running through nine impressions in eight years, has now reached a second edition, of which the copy for review is part of a second impression, would, however, seem to give grounds for hope that this educated public is not even now so small as we might, in atrabiliar moments, be inclined to believe; and will, we hope, encourage authors and publishers to give us more books of the same stamp. To praise such a book as "The Electron" is superfluous. Dr. Millikan is well known to be as skilful with his pen as in his laboratory. We need only add that the new edition contains fresh matter which brings his account of his subject well up-to-date, and readers of the first edition will certainly wish to see it.

Prof. Chwolson's scholarly volume "Die Evolution des Geistes der Physik 1873–1923" raises questions far too complex to be dealt with at the tail end of an omnibus review. He has been a close and not unfriendly observer and critic of the progress of physics throughout the period with which he deals. He believes that the last fifty years have seen not merely a growth in the content, but also a change in the spirit of the subject, which it is the object of his book to demonstrate The book is thus more than a résumé—it is a criticism, and to a science suffering somewhat from a surfeit of its own discoveries, and inclined a little, perhaps, towards swelled-headedness, a friendly dose of cold water may be not merely salutary but even welcome. Many students who have profited from Prof. Chwolson's monumental text-book will at least be glad to have his matured opinion of what they have done with their instruction. We should welcome an English edition of this thoughtful little book. Should some kindly publisher be willing to increase our indebtedness to himself by placing an English version on his list, we hope he will not be misled by the title of this article into classifying it as popular science.

Physico-Chemical Problems of the Cell.

La cinétique du développement : multiplication cellulaire et croissance. Par Dr. E. Fauré-Fremiet. (Les problèmes biologiques.) Pp. viii+336. (Paris: Les Presses universitaires de France, 1925.) 35 francs.

AS its title indicates, this book deals with the problems of development from the point of view of changes in the energy potential and the physico-chemical constitution of the animal organism A very wide field is covered embracing the experimental aspects of embryology and cytology, and the very numerous and various facts presented are, by the method of treatment, welded into one consistent whole. Apart from its originality of outlook, the book is undoubtedly of great value to all experimental biologists merely as a work of reference. The author's solution of the problem of what to omit will probably, in the main, meet with approval. It is at first sight strange to dismiss in a short footnote (p. 114) the evidence for the permanency of the chromosomes, but as information on this point is readily available in numerous text-books, the author has perhaps chosen wisely in omitting it here. The omission of any discussion on regeneration, with the exception of a short account of the healing of wounds, is more to be regretted. The problems of regeneration and those of development are undoubtedly closely allied, and the scattered facts and theories of regeneration could well bear such a critical review as the author has, in this book, bestowed upon other problems

The first three chapters deal, broadly speaking, with the physico-chemical constitution of the cell, and the changes therein, during growth and division, and to a large extent may be said to be based on Zwaardemaker's conception of the application of the phase rule to the problem of protoplasmic structure. The author admits frankly that in the present state of our knowledge the application of this rule can be only tentative. This conception has been used with admirable discretion, and perhaps its main virtue is that it has enabled the author to link together in one connected and extremely interesting whole the very considerable number of facts and theories here presented. Perhaps too much mystery is made of the nucleus-cytoplasm volume relationship; the discussion of this would have been greatly simplified by beginning from the obvious consideration that materials for nuclear growth can only reach the nucleus by first passing through the cytoplasm. Indeed, it may be regarded as certain that the raw food materials of the cell are not available for use by the nucleus until they have been very considerably altered by the cytoplasm. Obviously, then, after division of a cell there must be a lag in the rate of growth of the nucleus of the daughter cell as compared with its cytoplasm, since, except for the possible persistence of small quantities of nuclear "food" in the cytoplasm of the daughter cell, the nucleus has to wait for its supplies of food material until these are elaborated by the cytoplasm. Many, though not all, of the various changes in the nucleus-cytoplasm volume relationship are explicable in this simple manner. A minor point of criticism in this chapter is that the table given on p. 90 is by no means clear until reference is made to the footnote on p. 92. As it stands, the table will be taken to show the number of cells developing from a fertilised Strongylocentrotus egg in a given time at various temperatures, and proves little beyond the obvious fact that at low temperatures development is less rapid. The comparison intended is between larvæ of the same degree of morphological evolution reared at various temperatures, and shows that at low temperatures the larvæ contain fewer cells and relatively larger nuclei than larvæ of an equal degree of morphological differentiation reared at higher temperatures.

Chapter 4 deals with the very difficult subject of energy transformations during embryonic development. This chapter suffers somewhat from a plethora of cold facts, and is apt to leave the non-specialist with no very clear ideas on the subject. The blame for this may perhaps with more justice be laid on the subject than on the author, as the study of the energetics of development has as yet scarcely emerged from the chaos and multiplicity of disconnected facts which is the necessary but unpleasant beginning of most sciences. The remaining three chapters deal respectively with growth in metazoa, multiplication of Protozoa, and growth in tissue cultures. The chapter on Protozoa is, of three good chapters, the best, and provides a most excellent summary of its subject. In the chapter on tissue culture, the author is to be congratulated on having included such things as the healing of wounds and the growth of grafts, and on having shown the relationship of these phenomena with those of tissue culture *sensu stricto*.

The mathematical treatment adopted in many places throughout the book will be regarded by the non-mathematical biologist as a painful necessity, and to such may give some little difficulty. In some of the tables of figures the author has omitted to state the units to which his figures refer. Though reference to the context usually clears up this point with little difficulty, the omission is none the less annoying. But whatever minor faults this volume may contain, it is not only a fine work of reference, but also has in an eminent degree the still higher excellence of originating fresh ideas, suggesting new experiments, and fortifying that modern conception of biological inquiry the adherents of which are striving little by little, with progress however slow and doubtful, towards the ultimate goal of raising biology to the rank of an exact science; of explaining "vital" processes in terms of physical and chemical units.

J. G. H. F.

The American Coal Commission.

What the Coal Commission Found: an Authoritative Digest and Summary of the Facts about Coal. By Staff Members. Edited by Edward Eyre Hunt, F. G Tryon, and Joseph H. Willits. (Human Relations Series.) Pp. 416. (Baltimore, Md.: Williams and Wilkins Co.; London: Baillière, Tindall and Cox, 1925.) 25*s*. net.

THE need for a careful study of the many difficult problems presented by the coal industry led to the appointment towards the end of 1922 of the United States Coal Commission, which continued to function for eleven months, during which time it spent about 120,000*l*. and employed at one time more than 500 persons. The very voluminous records and findings of the Commission have been conveniently condensed in the present volume of a little more than 400 pages, in which are collected together the important portions in an eminently readable form. Its appearance at the present moment is particularly important in view of the fact that we, too, have a Coal Commission now sitting for the purpose of studying the same industry in Great Britain, and the findings of the American Commission will assuredly afford some useful guidance, though it is obvious that the problems in the two countries are in many respects widely different.

In the United States the essential problem is how to ensure an uninterrupted supply of coal to the industries and the people generally; in Great Britain the problem is how to bring down the cost of production of coal to such a level as to enable British collieries to compete successfully in the world's markets America is to some extent indifferent to the cost of production, because America is a self-contained country, producing within its own borders everything that is needed for the nation's well-being. In Great Britain, on the other hand, the cost of production is the dominating factor, because it is only by means of coal produced sufficiently cheaply to enable it and the various articles, for the manufacture of which it is indispensable, to be sold at competitive prices in the markets of the world.

In spite of this wide divergence in the character of the problems, it becomes evident upon investigation that the underlying causes which have given rise to them are very similar. The findings of the American Coal Commission are therefore not without their value for British investigators. It must, however, be pointed out that the American Commission has been careful to distinguish between bituminous coal and anthracite, and that it is only the former portion of the subject that finds any counterpart in Great Britain. Perhaps the most interesting sentence in the book is the record of the finding of the Commission that there is "no reason to believe that a dependable supply of coal at a reasonable price is inconsistent with reasonable conditions of life and citizenship for the miners, or with a reasonable return on judicious investments." In order to attain this most desirable consummation a number of recommendations were made, though it appears to have been fully recognised that, in the words of John Hays Hammond, who contributes a foreword to the volume, "There is no easy panacea for the troubled industry."

The most important recommendations were those addressed to the industry itself, and these include the development and efficient application of mechanical devices to replace hand loading, better control and co-ordination of underground operations, standardisation and co-ordination of the work of the individual mine-worker, standardisation of details of construction and dimensions of all mine equipment. In respect of Government action, the recommendations are mainly negative; thus compulsory arbitration and nationalisation of the mines were not recommended. Curiously enough, the British wage agreement, the termination of which has precipitated our coal crisis, comes in for approval. Finally, the fact is stressed that this is not a question to be fought out between the colliery owners and the coal miners alone, but that the public is vitally interested, and this last statement is even more profoundly true in Great Britain than in the United States. Hence comes the need for the public to receive authentic and unbiassed information on all matters concerning the coal industry, so that "guided by facts rather than rumours, by information rather than prejudice, the people will be able to exercise wisely the powers of the Government over this type of private business."

H. LOUIS.

Our Bookshelf.

(1) *Laboratory Manual in General and Pathogenic Bacteriology and Immunity.* By Prof. Veranus Alva Moore and Prof. William Arthur Hagan. Pp. xii + 252. (Boston, New York and London: Ginn and Co., 1925.) 8*s.* 6*d.* net.

(2) *Bacteriology: a Text Book on Fundamentals.* By Prof. Stanley Thomas. Pp. xiii + 201. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1925.) 12*s.* 6*d.* net.

(1) THE first of these books is intended to be a laboratory guide on bacteriology for veterinary students. It consists of practical exercises, and at the end of each exercise is a series of questions. The latter seem uniformly to have little or no bearing on the particular exercise. Thus Exercise No. viii. is headed "Making plate cultures: the Gram stain," but it contains no information about the Gram stain. Nevertheless, the student is asked the question at the end of the exercise, "What is the function of the iodine solution in the Gram technic?" The only answer to this question which we can find in the book is given in Exercise vii., in which it is stated that "little is known of the chemical process involved in the Gram stain." This kind of sample has not been particularly selected. It occurs more or less throughout the book. English examiners would not cordially accept an answer like this from a candidate.

(2) The second book is by Stanley Thomas, who is associate professor of bacteriology in Lehigh University, Bethlehem, Pa. It is a general account of bacteria and their actions. It is well written, covers a good deal of ground, and is for the most part accurate. The author's statements on the history of bacteriology require correction, and his chapters on pathogenic bacteria indicate that he is not so much at home with them as when he deals with bacteriology applied to public health.

The Strength of Materials: a Treatise on the Theory of Stress Calculations, for Engineers. By John Case. Pp. viii + 558. (London: Edward Arnold and Co., 1925.) 30*s.* net.

THE book under notice differs somewhat in its purpose from the usual text-books on the subject, in that little space is given to discussion of the physical properties of materials or to experimental work. On this account the author's sub-title, "The Theory of Stress Calculations," is perhaps more appropriate, expressing more correctly the scope of the work. The sequence adopted for the various branches of the subject is open to criticism, but the theoretical treatments covering a wide range of problems of real importance to the engineer are very complete, except in some of the more advanced portions of the work, as for example in the account given of the torsion of non-circular shafts, where the results of the theory are stated only.

In the later portion of the book a treatment is given of the temperature stresses in thick cylinders, and in view of its importance, the more general problem of the stresses in cylinders and discs due to any concentric temperature distribution, on the lines of Prof. C. H. Lees' work, might well have been included as it presents no great difficulties. A good abridged account of Prof.

C. E. Inglis's work on the transverse oscillations of beams is given, but the chapter on the whirling of shafts is scarcely satisfactory, as no account of this subject in a modern treatise can be so considered which omits to take account of the general question of the stability of the motion and the factors which govern it. The whole is none the less a welcome contribution to engineering literature. The numerous references to various authorities contained in the footnotes are not the least valuable feature of the book, and, in addition to sets of good examples at the ends of the chapters, a large variety of interesting and instructive practical examples are worked out in the text. E. H. L.

Air Ministry: Meteorological Office. The Weather Map: an Introduction to Modern Meteorology. By Sir Napier Shaw. (Published by Authority of the Meteorological Committee.) Sixth issue. (M.O. 225i.) Pp. 112 + 8 plates + 8 charts. (London: H.M. Stationery Office, 1925.) 1*s.* 3*d* net.

THIS publication was first issued in 1916 for the benefit primarily of those who were making use of meteorology in the War. The work has naturally grown, although only slight alterations are made in the present issue. A note on visibility has been added. The book is of the highest possible value to those who wish to obtain an intelligent interest in the weather and its numerous and complicated changes. The author, who has done much to place meteorology in its present position among the sciences, has achieved an immense success in placing modern meteorology so thoroughly and so simply before his readers. With the extensive broadcasting of the weather forecasts, many are wishful of obtaining an intelligent insight into the construction of the weather map and the weather changes indicated. The sequence of the weather is dealt with, and simple types are given showing the influence of time on changes of weather, winds, temperature, and pressure. Tables and maps are given for the reduction of the observations and show the average or normal conditions of the several elements for the whole or any part of the British Islands. A chapter is given on the upper air; it is stated that the world's height record in an aeroplane is 39,587 feet, achieved by M Callizo on October 10, 1924, at Villacoublay near Paris. The highest mountain climb was achieved by the climbing party on Mount Everest, seen on June 8, 1924, at a height of 28,230 feet. The ballon-sonde has enabled temperature observations to the height of 22 miles, and on many occasions up to 12 miles.

(1) *The New Matriculation Geometry.* By A. G. Cracknell and G. F. Perrott. Pp. x+303. (London: University Tutorial Press, Ltd., 1925) 4*s* 6*d*.

(2) *A School Geometry on "New Sequence" Lines.* By W. M. Baker and A. A. Bourne. (Cambridge Mathematical Series.) Pp. viii+307. (London: G. Bell and Sons, Ltd., 1925.) Books 1-3, 2*s.* 6*d.*; Books 1-5, 4*s.*

THE teachers who objected to the introduction of a "new sequence" in geometry on the grounds that it would merely mean the exchange of Euclid's yoke for another scarcely less objectionable, have evidently some justification for their fears. Both these books give no less than 120 propositions to cover the substance of Euclid I.-IV., in addition to which the former dismisses similar figures in 10 pages, and the latter deals adequately with the propositions of Euclid VI. and XI. Surely some of these 120 propositions could with advantage be treated as riders or, at any rate, a clear distinction should be made between propositions which the pupil is supposed to reproduce and those he is merely asked to understand.

It is interesting to note that the method of superposition flourishes as if nothing had been said to its detriment during the past twenty years.

The riders in both books are good and numerous, but in "The New Matriculation Geometry" the bulk of them are collected together at the end of the book.

Leitfossilien: ein Hilfsbuch zum Bestimmen von Versteinerungen bei geologischen Arbeiten in der Sammlung und im Felde. Herausgegeben von Georg Gürich. Vierte Lieferung: Leitfossilien der Trias Wirbellose Tiere und Kalkalgen, von C. Diener. Pp. ii+118+28 Tafeln (Berlin: Gebrüder Borntraeger, 1925.) 24 gold marks.

THE publication of this useful work on characteristic fossils has extended over a long period. Part 1 (Cambrian and Silurian) was issued in 1908; part 2 (Devonian) in 1909; part 3 (Carboniferous and Permian) in 1923. The portion recently published deals with the invertebrates and calcareous algæ of the marine Trias, and has the inestimable advantages of being the work of Prof. C. Diener, whose researches on Triassic cephalopods are known to all geologists and palæontologists. The treatment of the subject is strictly systematic; in each group of fossils the characters of the families and genera are given, with notes on some of the important species. The work is illustrated by numerous figures, mainly copied from the memoirs of recognised authorities, but those of the calcareous algæ are from original drawings by Dr Julius Pia. Short but useful bibliographies are given for each group of fossils. The work concludes with tables showing the stratigraphical divisions, and the ranges of the characteristic fossils, in all the principal regions of the world where the marine Trias is developed It is to be regretted that this part, like parts 1 and 2, is without an index.

The Mathematical Theory of Electricity and Magnetism. By Dr. J. H. Jeans. Fifth edition. Pp. viii+652. (Cambridge: At the University Press, 1925.) 21*s.* net.

THE fifth edition of an established text-book calls for little comment. The previous edition was marked by the introduction of a new chapter on the theory of relativity. The present volume has yet another new chapter on "The Electrical Structure of Matter," intended as an introduction to the quantum theory. It seems rather sad that this new chapter should have to confess that some of the conclusions in the earlier part of the book—as to the radiation of energy from an accelerated electron—are in contradiction with modern knowledge, and that the whole theory which led to those conclusions is in need of amendment, but such is the history of science The chapter will admirably serve its purpose of leading up to modern theory.

Transmutation of Elements.

A Transmutation of Lead (First Method).

SINCE the publication of my letter in NATURE of October 25, 1924, on the transformation of elements, I have continued the experiments in collaboration with Dr. A. Karssen.

The quartz lead-lamp, after being altered several times, was finally given the following definite construction (Fig. 1). The two legs are bent upwards, and the lower ends of one of the steel electrodes, one of which is provided with a piece of carbon, are ground to a tight joint into the legs, so that they can serve as cocks. The electrodes are connected with the legs of the lamp in a completely air-tight manner without the use of mercury. This lamp, containing, of course, also a storage vessel, is mounted on a stand provided with a wide copper tube with a series of gas burners to keep the lead in the lamp in a molten condition.

Further, the lamp is provided with two other copper tubes connected with a conduit pipe from the compressed air supply to cool those parts of the lamp which are heated too highly by the electric arc.

In our experiments we had to consider the possibility of the transformation of lead into mercury, which makes it desirable, of course, to avoid the use of a mercury air-pump and a mercury manometer. Therefore, the lamp initially was evacuated by a carefully cleaned metallic pump, connected with two U-tubes, placed in liquid air, and finally with a large vessel filled with coconut charcoal, also cooled in liquid air, by which method a high vacuum could be obtained. If not working in vacuum the pressure was measured by a glass spring manometer provided with a calibrated scale. Working under pressure, the connexion with the coconut charcoal vessel was broken, and pure nitrogen was admitted.

It is evident that in researches such as are mentioned here, the material used must be as pure as possible. The firm of Kahlbaum was so kind as to prepare for us an extra pure preparation of lead with the utmost care to prevent every contamination, especially by mercury vapour. In this preparation neither mercury nor thallium could be detected analytically.

The quartz parts of the lead lamp were cleaned by a solution of potassium dichromate and nitric acid, then steamed, and then finally heated to redness in a current of dried air. The metallic parts of the lamp, made of steel, after cleaning were heated to redness and the carbon valve underwent exactly the same treatment. *All these materials, examined spectroscopically, were shown to be completely free from mercury and thallium.*

The method of investigation used by us was as follows: After filling the storage vessel, the lamp and the lead were heated in high vacuum to redness. The lead oxide being dissociated, the liquid lead was as brilliant as mercury. Then the lead was brought into the lamp, and after ignition the spectrum was observed at 25 volt and 36 amp, by a Hilger quartz-spectrograph. Further, the spectrum of a quartz mercury lamp was observed, and also the scale in such a way that, to facilitate comparison, the different spectra were adjacent. Thus we obtained the spectrum of the lead in its initial state. After that we burned the lamp at 40 amp. and ± 80 volt for 10 hours. After having done this the lead was poured into the storage vessel to obtain thorough mixing; the lead was then brought into the lamp again, and after ignition the spectrum was observed at 25 volt and 36 amp. The result was that, whilst initially the lead spectrum showed only very weakly the mercury line 2536 in the ultra-violet, after 10 hours' burning the strongest mercury lines had appeared in the visible as well as in the ultra-violet part of the spectrum, and also the most characteristic thallium line, indicating a transmutation of lead into mercury and thallium.

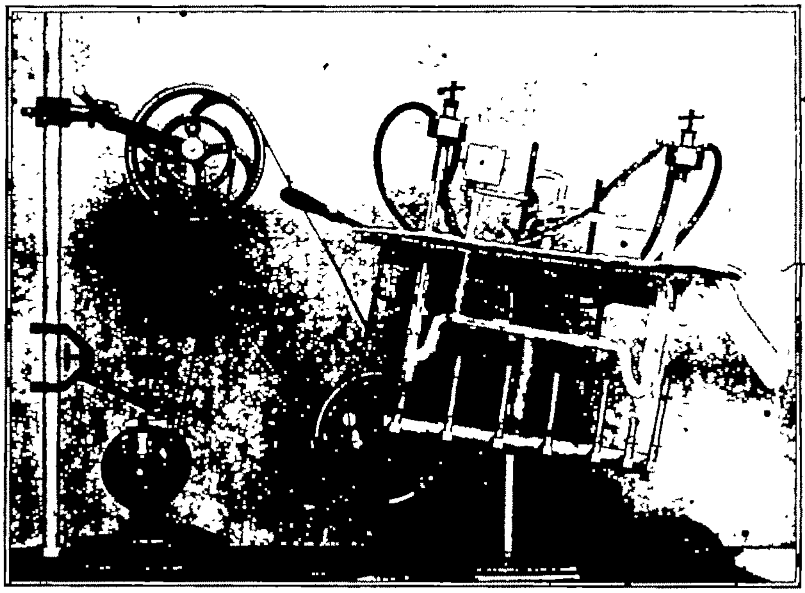

FIG. 1.—Quartz lead-lamp.

Since our experiments showed that a high current density is very favourable to this transformation, we used currents up to 60 amp., but that seemed to be dangerous, because only by intensive air cooling could melting of the quartz-lamp be prevented.

We thought it better, therefore, to change our method a little, by applying not a continuous electrical current but sparks of high current densities. Therefore, the lead lamp and the delivery tube with gas burners, and the cables and cooling tubes, were all mounted on the same stand, turning on a horizontal axle. While the lamp was kept oscillating by a mechanical arrangement as shown in Fig. 1, a current of high density was breaking and making. At make the current was 60–100 amp., and since the last contact is made by a very thin spout of liquid lead, the current density on the moment of breaking the current will be exceedingly high. This method was very successful. Since at the places where sparks are emitted a black film appears, it was necessary before observing the spectrum to clean the quartz tube as well as possible by burning the lamp half an hour continuously. After that the lead was poured into the storage vessel and then again into the lamp, as already mentioned, the spectra obtained now showed a much stronger transmutation, and after 9½ hours' sparking all mercury lines, even the very weak ones, were present.

Our purpose, of course, was to see what the result would be after continuing our experiments a very long time. In this case, however, we met a great difficulty, since the quartz became corroded strongly by the lead, forming a film of lead-silicate, blackened by silicon.

To make us independent of the formation of this film, at the place where the arc in the lamp is formed a quartz tube (observation tube) of 15 cm. length and 8 mm. diameter was sealed, the upper end of which was provided with a flat bottom.

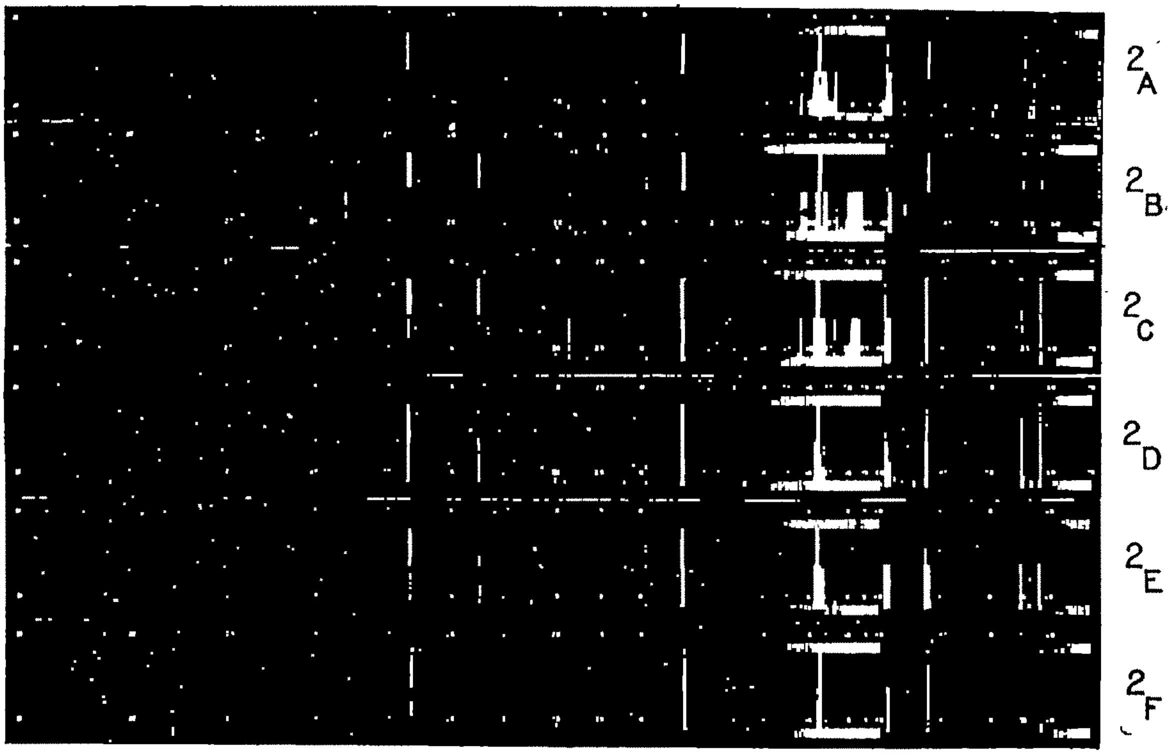

FIG. 2.—Spectra of lead with comparison spectra of mercury, the upper spectrum in each case being that of mercury. (Some of the very faint lines have not appeared in the reproduction.)

The light of the arc passing through the unattacked quartz-bottom, reflected by a nickel mirror, was directed to the quartz-spectrograph. Fig. 1 shows the observation tube and the nickel mirror. By this means the transmutation can be studied so long as the lamp stands.

Fig. 2 shows the results. The mercury spectrum is in each case placed above the lead spectrum. Fig. 2A shows the mercury spectrum at the top, and at the bottom the spectrum of the extra pure lead in the initial state. It is seen that this lead preparation is very pure: the lead spectrum does not contain mercury lines. The negative being always a little more distinct than the prints shows a very weak indication of the mercury line 2536, that is, the line which always appears in our experiments first.

Burning and sparking we obtained successively the photographs reproduced above as Fig. 2. 2B was after burning half an hour at high current density; 2C, after 2½ hour sparking; 2D, after 8½ hour sparking; 2E, after 12 hour sparking; and 2F, after 39 hour sparking.

We see in photograph 2B the green and the indigo mercury line, and some lines in the ultra-violet have already appeared. The line 2536 is strongest. The double yellow mercury line is not yet present. In 2C more mercury lines have appeared, and the lines already present in 2B have become much stronger. The double yellow mercury line has also appeared. In 2D and 2E the mercury lines are distinctly prominent over the lead lines in the lead spectrum. To make the results as convincing as possible the time of exposure in photographing the lead spectra was 20 minutes in the case of 2A and 2B, 15 minutes in the case of 2C and 2D, and 10 minutes in the case of 2E. Finally, in the case of 2F, the exposure was only 3 minutes, and now we see that the lead lines in the visible part of the spectrum have disappeared, and in the ultra-violet the lead lines have weakened. The mercury lines, however, are very distinct along the whole spectrum.

This, however, does not yet prove the transmutation to be strong, as it is known that a relatively small quantity of mercury can cause the spectrum of another element to disappear. But at all events our spectra show in a very convincing way the transmutation of lead into mercury. As to the thallium lines, it is very remarkable that these lines appear only if the spectrum is photographed directly, that is to say, not using the observation tube, but pointing the light emitted by the lamp directly to the quartz-spectrograph. This seems to be connected with the fact that thallium, like lead, is taken up by the quartz. So we state that the formation of a film of lead silicate results in a stronger lead spectrum if observed directly. This phenomenon will be referred to in another place.

A Transmutation of Lead (*Second Method*).

After having shown the transmutation of lead by the method mentioned above, we applied another very successful sparking method. Extra pure lead supplied by Kahlbaum was heated in a quartz tube up to about 800° for an hour, whilst a current of pure nitrogen was bubbled through. We thus obtained a lead preparation comparable with the lead in our lead lamp, in which it was heated to this temperature in a high vacuum. From the lead obtained in this way, two lead electrodes of 14 mm. diameter were made. Between these electrodes, mounted vertically at a distance of about 4 mm. apart in a vessel with a liquid dielectric, sparks at a voltage of 100,000 volt and 2 milliamperes were sent through the liquid for 12 hours.

The dispersed lead was partly at the bottom and partly in colloidal solution. The fine lead at the bottom of the vessel was collected, washed successively in pure benzene, alcohol, and ether, and finally dried in a desiccator. The metal in the colloidal solution was converted into nitrate by treating the liquid with pure nitric acid at 100°.

After evaporating the aqueous solution on a water bath, the nitrate was placed in a desiccator.

Both substances were examined. The method of analysis was substantially a method of Jannash (*Z. fur Anorg Chemie*, 12, 143 (1900)), as modified by us. Mercury eventually present is driven out by heating in a current of air and condensed in a glass capillary. Then iodine vapour is conducted over it, forming with mercury the red modification of the compound HgI_2. This extremely sensitive reaction, if applied to the electrodes as prepared by us from the extra pure Kahlbaum lead, showed that these electrodes were completely free from mercury, but the dispersed lead obtained by sparking in the circumstances mentioned showed a very distinct mercury reaction.

Consequently, also by this second method, the transmutation of lead into mercury could be realised.

Whether thallium is also formed is being examined.

Both methods mentioned above will be applied soon to bismuth, thallium, and other elements to be considered here.

In another letter we propose to give the results of the quantitative analyses and some theoretical considerations.

Selective Action of Polarised Light upon Starch Grains.

THE letter of Prof. E. C. C. Baly and Dr E. S. Semmens in NATURE of December 5, p. 817, on the selective chemical action of polarised light upon starch grains seems to me to raise a question of fundamental importance for optics. Is it possible to reconcile such an action with received views about the kinematic relations of polarised light?

Let us begin by considering a case where difficulty does *not* arise. Baly and Semmens refer to Padoa's observation that "crystals of *o*-nitrobenzaldehyde are selectively decomposed by polarised light, *provided that the crystals are correctly oriented to the plane of polarisation*" (my italics). I have not had the opportunity of consulting Padoa's paper, and know nothing of the details; but there is no obvious *a priori* reason why such an action should not occur: for the molecules in the crystal are all similarly oriented, and may well be less able to withstand a displacement in one particular direction than in the perpendicular one.

It is easy, however, to pass to a case where the difficulty does arise. Suppose the crystal pulverised, and the fragments shaken up so as to be oriented at random. They cannot now be all favourably oriented to the polarised beam. Some of them, on the other hand, will be more favourably oriented to a beam polarised at right angles to the first; and if both beams were present, they would presumably add their effect. We can get the two beams instead of one by simply *removing the polariser*, or, in other words, using unpolarised light. It seems clear that in this case polarising the light (with inevitable loss of half of the intensity) must *diminish* the chemical action. The same reasoning seems to apply with equal force to the case of the starch grains, assuming that these are oriented at random.

Great caution is required in weighing any *a priori* reasoning against what seems the result of direct observation. Both, however, involve the human element, and both are therefore liable to be wrong.

RAYLEIGH.

Terling Place, Chelmsford,
December 14.

IT was with much interest that I read the letter relating to the action of polarised light on starch hydrolysis contributed to NATURE of December 5 by Prof. Baly and Dr. Semmens. This letter, since the writers refer to a short "note" by myself in the *Annals of Botany* (July 1925), calls for a brief reply.

Prof. Baly and Dr. Semmens are, like myself, under misapprehension. I desired to call in question, not the possibility of the phenomenon occurring, but the trustworthiness of the evidence put forward by these authors in their paper (*Proc. Roy. Soc.*, 97 B, 250, 1924). The fact that a large amount of evidence in favour of the occurrence of this phenomenon may have been published by the authors or others elsewhere appears to me to be of great interest but quite irrelevant in so far as objection is taken to the "note" for which I was responsible. For example, Weigert's observations on the effect of polarised light on the photographic plate do not make me any readier to believe that potato starch grains in weak diastase solution, after four hours' exposure to polarised light, as a result of hydrolysis will present the appearance shown in Fig. 3, Plate 12, in the paper criticised. I am also dreadfully puzzled to understand why this figure, described in the text as showing "hydrolysis obtained with light polarised by a Nicol prism," was published, if it was not intended as evidence. The "complete disappearance of the grains" I have not observed with potato starch even after some days in strong diastase solution: in my experience a kind of "starch shell," which does not give a blue colour with iodine, persists obstinately.

Since an experiment of my own is cited (which was additional to a repetition of any described by the authors) in which a gelatine film was used, I may perhaps point out that the starch grains were resting on the surface of the gelatine, which was used merely as a convenient adhesive surface to prevent the grains from moving about, and that the polarised light reached the grains without passing previously through the gelatine film. But I should regard any such experiments that give a negative result as of little importance compared with one conclusive experiment of which the result was consistently positive: and no doubt Prof. Baly and Dr Semmens will agree with me in this. The position remains unsatisfactory, however, until the reason for the negative result receives satisfactory explanation.

As one who has suffered from the painful effects of traversing in full sun snowfields in the Alps, I was interested to learn that this effect was due to "the well-known influence of polarised light." I do not feel, however, that an argument of the form—"certain effects are produced by light on crossing a snowfield—some of this light is polarised—therefore the effects are due to the polarised light"—will withstand logical analysis.

Bedford College,
Regent's Park, N.W.1.

The Occurrence of Dwi-Manganese (At. No. 75) in Manganese Salts.

As the present writer is responsible for the polarographic investigations of solutions containing dwi-manganese (see letter by Dolejšek and Heyrovský, NATURE, 116, p. 782), he alone replies to the criticism of the above letter by Mr. A. N. Campbell (NATURE, 116, p. 866). This criticism shows a misunderstanding of what the polarographic-electro-analysis with the dropping mercury cathode really means. First of all, the present author's potentials refer, as expressly stated, to the calomel—not absolute—zero, and thus, of course, do not agree with those obtained by Mr. Campbell, since the present author's special electrolytic method is based on an almost currentless reversible electrolysis which differs widely from ordinary electrolytic methods (see, for example, *Tran. Far. Soc.*, 19, p. 692, 1924; *Rec. Trav. Ch. Pays-Bas*, 44, p. 488, 1925). The over-voltage on the pure mercury cathode beads is so large that hydrogen begins to be deposited from a deci-normal hydrionic concentration at − 1·20 v. from the calomel electrode (*Rec. Trav. Ch. Pays-Bas.*, 44, p. 503, 1925), and at the acidity of the solutions used in the dwi-manganese investigations, at − 1·3 v. to − 1·4 v., *i.e.* far behind the point of deposition of element 75. Variation of hydrion concentration from 0·1 n to neutral solution produced no effect upon the "75" hump, neither was its shape or position affected by polarising the sulphate or the chloride. Solutions of manganese sulphate which were freed from the two impurities by means of the electro-chemical deposition described in the first letter showed no hump whatever before the deposition potential of manganese at − 1·35 v.

Solutions were further obtained by subliming volatile chlorides from a fraction rich in "75," and these showed on polarograms the corresponding humps without any manganese in solution. The formation of manganese tetrachloride at the large mercury anode used in this method is out of the question, and it is equally impossible to superpose an alternating current with this delicate arrangement.

Polarograms of sodium sulphate have been frequently studied (*Rec. l.c.*, p. 493, 600), and show the same flat curve as those for sodium chloride, bromide and hydroxide.

Altogether about 400 polarograms were obtained, by the author and five collaborators working on three different pieces of apparatus in the dwi-manganese research, and checked by polarising solutions containing additions of different metallic salts to ensure that the new hump was due to a metal not hitherto identified. Whenever this hump is very prominent, the *L* lines of element 75 invariably appear in the X-ray spectra obtained by V. Dolejšek, and the combination of the two methods is now used as a guide in the analytical enriching of the solutions in element 75. Finally, the "75" hump agrees well with the deposition potentials at the dropping mercury cathode expected for the triad 25, 43, and 75, since in all analogous examples the deposition potentials of the metals in a triad become more positive by 0·1 v. to 0·2 v. with increasing atomic weight.

For a better understanding of the above explanations Mr. Campbell is referred to the seventeen papers dealing with this special electrolysis already published in English, and particularly to the Brauner jubilee number of the *Rec. Trav. Ch. Pays-Bas*, 44, pp. 488-600.

J. HEYROVSKÝ.

Institute for Physical Chemistry,
The Charles' University, Prague,
December 15.

MR. A. N. CAMPBELL in his letter to NATURE (Dec. 12) questions the validity of Dolejšek and Heyrovský's conclusions (NATURE, Nov. 28) that the second "hump" in their manganese deposition curve is due to the presence of small amounts of dwi-manganese.

In his letter Mr. Campbell assumes that the Czech authors used a platinum cathode, whereas it was Heyrovský's "dropping mercury cathode." As Mr. Campbell does not appear to be acquainted with Prof. Heyrovský's apparatus, I should like to direct his attention to an account of it in the Brauner jubilee number of the *Recueil des Travaux Chimiques des Pays-Bas* (May 1925). In his general introduction to a series of researches with this apparatus, Prof. Heyrovský pointed out, with examples, that the method he used was capable of detecting impurities down to concentrations of 10^{-6} gram-equivalents per litre. This has not been controverted.

Dolejšek and Heyrovský's interpretation that the "hump" in their manganese deposition curves was due to traces of dwi-manganese in "pure" manganese sulphate is supported by the isolation of the oxide of the new element from manganese sulphate and chloride by Mr. F. H. Loring and myself (*Chem. News*, Oct. 30, Nov. 27). By an entirely independent method we have been able to obtain about a gram of what we believe is fairly pure higher oxide of dwi-manganese.

Prof. Heyrovský's "dropping mercury cathode" does not appear to have received in Great Britain the attention it merits, although the writer of the section on general and physical chemistry in the Chemical Society's "Annual Report," 1924, mentions in connexion with it (p. 21) that there is no indication of a surface film being formed on it. This would invalidate Mr. Campbell's contention.

The Plant as a Measure of the Habitat.

IN NATURE of October 31, p. 656, appears a note concerning the plant as a measure of the habitat, wherein reference to "The Phytometer Method in Ecology," by Clements and Goldsmith, is made.

The subject of the complexity of the individual plant as a recorder is correctly touched upon, and opinion is expressed that probably it will be long ere physical instruments can be dispensed with in plumbing the possibilities of the environment

As workers in phytometry have been comparatively few, and are almost entirely American, it may be worth while to record very briefly indications as to the utility of the phytometer, obtained by me as the result of independent work.

South African native tree seedlings (*e.g.* those of *Ocotea bullata*, *Olinia cymosa*, *Olea laurifolia*, *Platylophus trifoliatus*, *Cunonia capensis*) are being tested as phytometers, the growth and transpiration responses under both natural and artificially produced habitats receiving initial attention. The results so far are distinctly favourable to the use of the plant as habitat measure; a short and preliminary account is to be published in the near future. For the forester, phytometric cultures, either free or under control, seem likely to prove valuable in returning information regarding the habitat as it impresses itself upon the plant, in throwing light on practices and processes either detrimental or conducive to the production of the optium yield from particular localities, and in indicating the species best suited to the areas to be planted.

By many it is realised that the most elaborate measurement of the physical factors of the habitat by instrumental methods usually does not even approximately inform the investigator as to the nature of that habitat as it influences the living plant itself. The plant is the truest measure of the effects of the complex produced by the integration of the several habitat factors. Provided that points of such importance as the careful selection of suitable types of plants, the employment of large numbers of individuals so that abnormal ones can be eliminated, and the study of the several responses of the plant in conjunction with physical apparatus, receive careful attention in the first instance, it does not seem too optimistic to believe that, with increased knowledge of the behaviour of selected species, the phytometer of itself will give intelligible quantitative information as to the nature of the habitat.

The value of the phytometer for analyses of habitat and vegetation processes alike is likely to be as great as the study of this grand subject is alluring.

The Principal Series of the Copper Arc Spectrum.

The second pair of the principal series of the arc spectrum of copper has been calculated by Randall (*Astro. Jour.*, 34, 1, 1911) as 2025·73 and 2024·42 (Rowland scale). Kayser and Runge (Kayser, "Handbuch der Spectroscopie," vol. 5) observed only one line at 2025·08 (I. Å.), while two lines in this region have been photographed by Rubies (*An. Soc. Esp. Y Quim*, 15, 432, 1917), and their wave-lengths given in Fowler's Report on Series in Line Spectra as 2025·1 and 2024·11 (presumably on the Rowland scale). Shenstone (*Phil. Mag*, 49, 951, 1925) in his low voltage arc work found only one line and gives its wave-length as 2024·33.

Recently in this laboratory photographs of the arc spectrum of copper under varying conditions have been taken on several large quartz spectrographs. The dispersion of these instruments at λ 2025 is approximately 0·8 mm. per Ångström unit. The exposures taken varied from 15 to 30 minutes. The current strength of the arc was 3 amperes on a 220 volts circuit.

When the middle of the arc was projected on the slit of the instrument, the 2024 line alone was recorded. When the whole image of the arc was projected, both lines were recorded, but the 2025 line was shown at the poles only. In all photographs the 2024 line was shown reversed. A plate of the spark spectrum showed only 2025. This agrees with Hasbach's spark work.

Independent calculations were made from photographs taken on three separate instruments. Interpolations were taken from a Hartmann formula based on the lines 2043·71, 2035·74 and 1999·95 (Hasbach, Kayser and Konen's "Handbuch der Spectroscopie," vol. 7). The values of the 2025 line agreed to 0·01 and those of the 2024 line to 0·02. Schumann plates were used. The following table contains our measurements, together with other known values. All wave-lengths are reduced to I. Å.

Table I.

	λ.	λ.	$\Delta\nu$
Randall (calculated) . .	2024·33	2025·67	32·7
Kayser and Runge . .	..	2025·08R	..
Rubies	2024·05	2025·04	24·1
Shenstone	2024·33	..	..
Hasbach	..	2025·36	..
Simeon and Dreblow .	2024·19R	2025·34	28·1

Our observed value of $\Delta\nu$, which is not expected to be in error by more than ±1·0, is notably less than Randall's calculated value.

From the results given above it is concluded that the 2024 line is a true arc line, being reversible and present in the centre, that the 2025 line is a spark line, and that therefore they do not constitute the second pair of the principal series.

The Action of Silica on Electrolytes.

Owing to absence from the laboratory during the summer, I have only recently been able to make experiments on the effect of silica on acids, using silica prepared as described by Prof. Mukerjee in his letter to Nature of August 29. The silicon tetrachloride was added to water in a silica dish and the mixture dialysed until the specific resistance rose to 120,000 ohms. It was then dried at the air temperature without the use of any desiccating agent. I have been unable, however, to detect in this product the slightest adsorbing power for hydrochloric acid. In his letter of April 4, Prof. Mukerjee gives figures from which I infer that he found that silica could take up more than 1 per cent. by weight of hydrochloric acid. I used one gram of silica and 100 c.c. of N/500 acid and should easily have detected the adsorption of less than 0·0004 gram hydrochloric acid (*i.e.* 0·04 per cent. by weight) by the conductance and *p*H measurements used. But not the slightest sign of removal of hydrochloric acid from solution was obtained.

I do not know whether Prof. Mukerjee has modified his views since April 4, as in his last letter the only experimental evidence suggested is that it is easier to remove traces of hydrochloric acid from silica by means of potassium nitrate solution than water. This is a very different matter from that which has been under discussion, and I will not take up space with a consideration of the various possible explanations. I am only concerned with the direct question as to whether or not pure silica can remove acids from solution, and I have been unable to obtain any evidence that it is able to do so.

One point has to be borne in mind when making these experiments: silica, prepared as above and partially dehydrated, retains much moisture (mine contained 20 per cent. after air drying for a week), which may dilute quite noticeably the solution to which it is added, and I have always corrected for this. The correction may be important in some cases, although in these experiments the quantities of reagents have been chosen so that it is very small.

The Evolution of the Stars.

By J. H. JEANS, Sec. R.S.

ABOUT a year ago (NATURE, December 6, 1924) reasons were given for supposing that the source of stellar radiation is to be found in the annihilation of stellar matter. Subsequent investigation suggests that the same hypothesis can clear up the puzzle of stellar evolution and of the spectral changes of a star.

In the early days of stellar spectroscopy, the spectrum of a star was believed to be an index to the star's age. That the spectra of different types of stars showed lines of, say, hydrogen, calcium, and titanium oxide, was explained by the supposition that as a star aged, its composition changed, by transmutation of the chemical elements, from hydrogen into calcium, from calcium into titanium oxide, and so on. We know better now; the researches of Saha and others have shown that a star's spectrum is an index only to the temperature of its surface. The solar spectrum shows calcium lines merely because the sun's outer layers happen to be at a temperature at which calcium atoms are very active in absorbing and re-emitting radiation; if the temperature of these layers were suddenly doubled, their spectrum would consist mainly of hydrogen lines, while if the temperature were halved, the spectrum would be dominated by the titanium oxide bands. The various types of spectra might quite well be expressed merely as temperatures, except for some outstanding difficulties as to the correct calibration of the temperature scale. Thus the problem of explaining the spectral changes of a star reduces to that of tracing out the sequence of temperatures assumed by its surface.

When we attempt to interpret radiation in terms of the annihilation of matter, the first observational fact that confronts us is that the radiations of the stars are nothing like proportional to their masses; for example, the very hot star V Puppis radiates nearly 1000 ergs a second for each gram of its mass, the sun about 2 ergs, and the earth certainly less than $\frac{1}{10000}$ erg. The transformation of matter into radiation clearly proceeds at very different rates in different bodies.

Our first impulse is perhaps to conjecture that the rate of transformation may be expedited by high temperature. But considerations of stability are found to prohibit any substantial effect of this kind. We can see in a general way that if a rise of temperature resulted in more rapid transformation, then any slight local excess of generation of energy, by raising the temperature, would force a still greater excess generation of energy, and so on without limit. Precise mathematical investigation (*Monthly Notices, R.A.S.*, October 1925, p. 914) shows that the observed stability of the stars permits of at most a very slight increase of this rate of transformation with temperature, and even this seems to be ruled out by physical considerations. Since matter is atomic, its annihilation must also be atomic, the annihilation of the smallest unit, a proton and electron, producing 0·0015 ergs of energy. This will form one quantum of radiation of wave-length $1 \cdot 3 \times 10^{-13}$ cm., which corresponds to a temperature of 7,500,000 million degrees. The temperature of a star's interior, some ten or twenty million degrees, is perfectly insignificant by comparison, and must be deemed quite incapable of affecting the process of transformation either way, at any rate by direct methods. We must accordingly suppose that matter is transformed into radiation by a spontaneous process, which proceeds, like radioactive transformations, without any regard to temperature or density. Newly generated radiation will have a wave-length of $1 \cdot 3 \times 10^{-13}$ cm. or less, but will soon become "softened" by interaction with matter and will degenerate into ordinary temperature-radiation before it has travelled far through a star. Part of the radiation generated in astronomical bodies of very low density may, however, escape into space as "hard" radiation of wave-length of the order of 10^{-13} cm.; this may be the origin of the highly penetrating radiation recently investigated by Millikan.

The great range of values of radiation per unit mass cannot, then, be traced to the variations in the physical conditions of different stars; to account for it we have to suppose that stars consist of a mixture of different types of matter which radiate at different rates, and that the proportions of the mixture vary from one star to another. Those types of matter which radiate most energetically are, of course, also those which annihilate themselves most rapidly, and so are the first to disappear as the star gets old. A young star, containing a greater proportion of these types than an old star, ought to emit more radiation per unit mass. This is in actual fact observed to be the case. Our sun, then, radiates less energy per unit mass than V Puppis simply because it is seven million million years older, and in this interval the elements which are responsible for most of the radiation from V Puppis have disappeared from the sun.

Since the process of transformation is a spontaneous one, it follows that if we know the composition of a star at birth and the rate of transformation of each of its constituent types of matter, we can trace out the changes in its composition throughout its whole life; the problem is similar to that of tracing the changes of radioactivity in rocks. Knowing the star's constitution at each instant of its life, we can, of course, deduce its rate of emission of radiation.

A mathematical study of the conditions of stellar equilibrium (*Monthly Notices, R.A.S.*, January, March, and June 1925) shows that the mass M, rate of emission E, and surface-temperature T of a spherical star in equilibrium are connected approximately by an equation of the form

$$2\tfrac{1}{2} \log E = \phi(M) + c \log T + \text{ a constant,} \qquad (1)$$

where $\phi(M)$ is a function of the mass, which is roughly proportional to $\log M$.

If this equation were accurately instead of only approximately true, the problem of tracing a star's evolution would be very simple. Corresponding to any assumed composition of the star at birth we can, as we have just seen, trace out the sequence of changes in the mass M and the emission E. At each instant the star will adjust itself so as to be in equilibrium by selecting a surface-temperature T such as to satisfy equation (1). The value of T given by this equation must accordingly determine the star's spectrum at every instant and the problem is solved.

It may seem almost incredible that the theoretical solution of the problem of stellar evolution should be so amazingly simple, yet such appears in actual fact to be the case, except for certain secondary complications, five of which we now discuss. These secondary complications impart incident and richness to the problem; it is because they intervene just where observation shows them to be needed, and because they give just the requisite modifications to the main solution, that we can feel confidence in the latter.

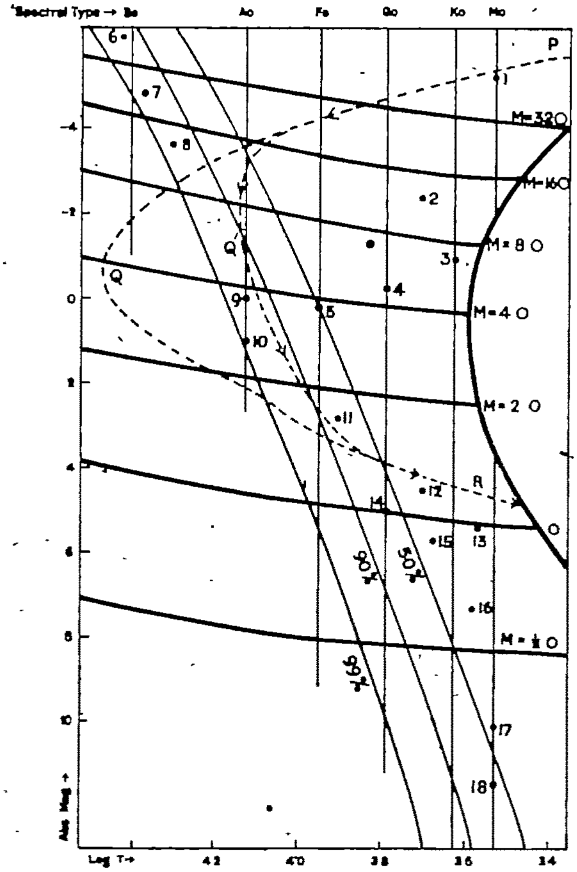

FIG. 1.—The stars, which are those shown by Russell in his diagram in NATURE (August 8, 1925), are as follows: 1, Antares; 2, δ Cephei; 3, Arcturus; 4, 5, Capella; 6, Plaskett's star; 7, V Puppis; 8, Y Cygni; 9, β Aurigæ; 10, Sirius; 11, Procyon; 12, 13, α Centauri; 14, Sun; 15, 16, ξ Bootis; 17, 18, Kruger 60.

I. Equation (1) is based on the conception of a star's interior put forward by the present writer in 1917, according to which the atoms are very largely disintegrated, as a result of high temperature, into their constituent electrons and nuclei, these now playing the rôle of "molecules" in the quasi-gas of which the star is formed. If the temperature were so high that every atom was completely disintegrated, equation (1) would be strictly accurate, c probably being equal to 2, the value given by Kramers' and Eddington's formulæ for stellar opacity. Actual stars are not so hot as this, so that c is somewhat less than 2. For average stars like our sun the value of c appears to be about unity, while for still cooler stars c may be negative.

Now the investigation of the star's dynamical stability shows that a configuration is stable (within limits to be mentioned later) if c is positive, but is definitely unstable if c is negative. A star becomes unstable as soon as it has cooled so far that c becomes negative.

The solution of equation (1) may be exhibited graphically as in Fig. 1. In this diagram $\log T$ and $-2\frac{1}{2}\log E$ (the star's absolute magnitude) are taken as horizontal and vertical co-ordinates. Equation (1) gives a value of M corresponding to each point in the diagram, so that each point represents a configuration of equilibrium for a star. The hottest stars are to the left of this diagram, the coolest to the right; the most luminous (which are also the most massive) are at the top, both mass and luminosity decreasing as we pass downwards. If c were strictly constant and positive, the curves along which M has constant values would be a series of parallel straight lines slanting upwards to the left. When the slight variations in c are taken into account, these lines run in the way shown by the thick lines in the diagram, the unstable parts for which c is negative being omitted. The thick curve on the right passes through the points at which c changes from positive to negative and so marks the limit between stable and unstable configurations.

Every astronomer will at once grasp the significance of this curve and of the hole it makes in the range of stable configurations. In 1913 Hertzsprung showed that the M-type (or red) stars fall into two clearly divided classes—stars of high luminosity which he called giants on account of their great size (a large surface-area being necessary to discharge so much radiation), and stars of low luminosity, the dwarfs. Between these two groups of stars lay a great gulf. Later, Russell, Adams, and others showed that the gulf extends to other spectral types, probably up to about $K4$. The theoretical curve which bounds the region of instability in our diagram cannot be drawn with great accuracy, but there seems little room for doubt that it must coincide with the boundary of the gulf between the giants and dwarfs. If so, there is a very simple reason for this gulf; stars cannot exist inside it because they would be unstable.

II. Every point of the diagram shown in Fig. 1 represents an equilibrium configuration for a star; as a star's evolution proceeds its representative point moves, and its evolutionary career can be recorded by a curve. On tracing out mathematically the evolution of a typical star in the way already explained, the evolutionary curve is found to be roughly parabolic and oriented like the dotted curve PQR in the diagram. The temperature of the star first increases until it attains a maximum at Q, then turns and decreases continuously, precisely as described by the "ascending and descending temperature" series of Lockyer. In time the star runs into the region of unstable configurations, as at R in the diagram.

When this happens, the star's internal generation of energy has become inadequate to supply its loss by radiation. Ordinarily a star would remedy this by expanding or contracting, but in this particular instance the star is already in a configuration in which its loss by radiation is a minimum, so that any change, whether in the direction of expansion or contraction, merely increases the rate of loss which is already too large. Equilibrium is no longer possible, and the star has to make good the deficiency in its generation of radiation by drawing upon its store of gravitational potential energy. It contracts rapidly.

The fundamental equation (1) was derived on the supposition that the gas pressure inside the star conforms to Boyle's law. The gas-molecules are, however, free electrons the diameters of which are far smaller than those of true molecules, whence it results that the stellar gas can shrink to enormously higher densities than ordinary gas before Boyle's law begins to fail. Eddington has suggested that this probably gives an explanation of the amazingly high densities observed in the stars known as "white dwarfs." The surfaces of these stars are at high temperatures and their radii so small that their densities must be thousands of times that of lead. The star the career of which we are following, when once it has become unstable, must continue to shrink until Boyle's law no longer holds, even for those absurdly small molecules, the free electrons. It becomes a white dwarf.

Thus our scheme of stellar evolution demands white dwarfs and provides a niche into which they fall naturally and inevitably. At the same time it suggests views of the physics and evolution of the white dwarfs which differ somewhat from those hitherto held. Eddington and Russell have considered the white dwarfs merely as extreme cases of ordinary stellar configurations. That the two or three white dwarfs so far detected are comparatively similar to one another must, on their view, be regarded as accidental. Our theory, on the other hand, implies that the white dwarfs form a separate and detached colony; they ought all to be rather like one another, and there should be no continuity with ordinary stars. As regards their evolution, the white dwarfs have been described as the oldest stars extant, "vestiges of an earlier creation," and so on. Our view of their evolution implies that they are neither older nor younger than the great majority of stars; they have merely been more unfortunate. The white dwarf state is a sort of bankruptcy court into which a star falls when it is unable to make both ends meet in the matter of radiation. When the original Sirius broke up into Sirius *b* and Sirius *f*, the former contrived to keep most of the matter which was easily transformable into radiation, hence the present splendour of Sirius *b* and the unhappy condition of Sirius *f*. In such cases as α Centauri and Kruger 60 there appears to have been a fairer division of radiation-producing material.

III. The typical evolutionary path PQR in our diagram penetrates regions near Q in which no stars are found. A star at Q would have practically all its atoms stripped bare of electrons, while calculations on actual stars show that very few have more than about 95 per cent. stripped bare. (The slant lines in the diagram show the proportion of bare nuclei calculated for an assumed atomic number 20.) The obvious interpretation of the observed facts is that in some way the evolutionary paths are turned before they reach regions of, say, 99 per cent. of nudity.

If the annihilation of matter is a quantum process of the kind I originally conjectured (Nature, December 6, 1924) this would happen automatically, for the baring of each nucleus would represent a loss of energy-generating power, and a star with all, or too many, of its nuclei stripped bare would leave off generating energy until sufficient atoms had re-formed. The typical evolutionary path in our diagram must no longer be taken to be PQR, but some such path as $PQ'R$.

The belt of configurations in which, say, from 80 to 99 per cent. of the nuclei are bare forms a sort of common envelope to most of the evolutionary tracks in the diagram. There ought then to be a great concentration of stars in this belt. This is in agreement with what is observed, for the calculated position of the belt, as shown in our diagram, coincides very closely with that of the main sequence of Eddington and Hertzsprung, which, besides forming a boundary in the direction of high temperature, is conspicuous for its great concentration of stars.

IV. It can be shown (*Monthly Notices, R.A.S.*, June 1925) that when a star breaks into two by fission, each constituent must assume a higher temperature than the original temperature of the parent star. The increase of temperature is generally sufficient to throw both constituents into the main sequence, after which the loss of energy-generating power will, as already explained, prevent their becoming still hotter. This explains why both constituents of newly formed binaries are generally found to lie in the main sequence.

A star such as Antares (No. 1 in Fig. 1) may reach the main sequence by travelling along a normal evolutionary path such as PQ' for about a million million years, or, in the event of fission occurring, may jump to it almost instantaneously, forming a binary star such as V Puppis (No. 7 in Fig. 1).

V. The stars in the region of P in our diagram are red giants of enormous size and very low density; they are almost all variable stars. Mathematical analysis shows that stars in this region may be affected by a special type of instability, not so far mentioned. This would show itself in a tendency to develop pulsations of practically unlimited amplitude, and there appears to be some prospect of explaining long-period variability in this way. The short-period variables and the Cepheids may possibly be stars actually in process of fission, as is suggested by their position in the diagram. Such conjectures need to be tested very thoroughly before they can be accepted, but it is at least clear that the proposed theory of evolution provides a place quite naturally for these two main types of a stellar variation.

Each of the foregoing modifications of the simple theory has been demanded by theoretical considerations, and each has been found to provide a natural, and almost inevitable, explanation of one outstanding feature of observational astronomy, as follows:

I. Giant and dwarf stars.
II. White dwarfs.
III. The "main-sequence."
IV. Early spectral types of newly-formed binaries.
V. Variable stars (conjectural).

It seems fair to say that no other theory of evolution gives a tenable explanation of even any one of these five features. This is the case for the proposed theory.

If a star, in breaking up by fission, divided its different ingredients proportionally between its two constituents, it is easily shown (*Monthly Notices, R.A.S.*, June 1925) that the fainter constituent would be of earlier spectral type than the brighter. This arrangement prevails in many newly formed binaries, but not in all (*cf.* Leonard, *L.O.B.* 343, 1923), and it is clear that in many cases, as in that of Sirius already discussed, the more massive constituent must have kept an undue share of highly radiating material; an extreme case of this kind is provided by the sun and earth. The situation is consistent with the supposition that the highly radiating material is of exceptionally high atomic weight and is therefore left in the more massive star when the lighter one is formed by drawing off the outer layers of the original star. Newly created matter probably contains elements of atomic weights far higher than any known on earth; it may even consist entirely of such elements. Our terrestrial elements are merely a residue of material which is practically non-transformable—dead ashes for the most part, although possibly the radioactive elements still retain some vestige of the powers of primeval matter. For one brief moment it seemed possible that cosmogony might teach us how to obtain almost boundless supplies of energy by the annihilation of quite insignificant fragments of matter, but this apparently is not to be. So far as we can at present see, Nature has arranged that the energy-producing elements shall be kept out of the reach of man; while he may watch the process of transformation going on in the stars, he will never be allowed to operate it himself. Whether this is to his advantage or disadvantage, who shall say?

The Relative Age of Rocks containing Fossils.

By Sir ARTHUR SMITH WOODWARD, F.R.S.

DURING recent controversies as to the evidence for the evolution of life in past ages, it has been stated that geologists arrange the fossil-bearing rocks in a "purely artificial" manner, not necessarily in the order in which they are found superposed. It has even been asserted that when the fossils occur in successive layers in an order which an evolutionist would say is the reverse of that expected, the rocks are assumed from this criterion alone to have been disturbed and turned upside down. The progressive development of life which a geologist recognises, indeed, is said to be imaginary and not proved by the observed order of superposition of the rocks.

Such statements are based on a complete misunderstanding of the facts. The science of geology originated, and the order of nearly all the principal layers of sedimentary rocks was first determined, on the unstable western edge of the continent of Europe. In this region from the beginning of geological time there have been frequently repeated downward and upward movements leaving records in sediments of the successive seas which overflowed and retreated. The sedimentary rocks have been tilted and their edges worn away in such a manner that their order, or relative age, is easily observed. Their succession in fact is so clear that it has been possible in several cases to follow the changes of material in one and the same layer—the sands and gravels which were deposited near the shore, the mud farther out, and the remains of calcareous skeletons forming limestone in the clear water of the open sea. As an illustration may be mentioned the lower Carboniferous deposits, which are open sea limestones in central England but gradually pass into estuarine sands and clays with beds of coal in the south of Scotland, where there are only occasional beds of limestone containing approximately the same fossils as the great marine deposits farther south. More than a century ago, when almost all naturalists believed in "special creation" and there were no accepted theories as to the order of "creation," the succession of the rocks in England and Wales was made out by William Smith from actual observation of their superposition. Later geologists merely elaborated details, and made more extensive collections of fossils. Geologists on the present European continent found the same general succession in their several countries, only varied by local circumstances; some additional layers being intercalated in the typical British series, others omitted, and some being represented by different rocks. Allowing for the differences in sediment and its amount which would be deposited in different parts of the same sea and adjacent estuaries, the succession was discovered quite clearly by observations in the field.

It was not until the field-work was far advanced that the fossils were studied in detail and found to indicate distinct progress in the development of life on the earth. None but animals without a backbone have ever been found in the oldest fossiliferous rocks; fishes are known to have flourished long before any lung-breathing backboned animals; the cold-blooded amphibians and reptiles came successively before the warm-blooded birds and mammals; man appeared at the end. In several groups, too, fossils collected from rocks of which the relative age is definitely known from observation of the layers in the field, show that the lower grades appeared before the higher grades. This became evident so long ago as 1836, when Buckland in his Bridgewater Treatise remarked on the interest of the oldest known mammals from the Stonesfield Slate of Oxfordshire as belonging to the lowly pouched group of marsupials. He stated that "the analogies afforded by the occurrence of the more simple forms of other classes of animals in the earlier geological deposits would lead us to expect also that the first forms of Mammalia would have been marsupial."

When geologists began to study the marine fossil-bearing rocks in other parts of the world, especially North America, they discovered differences in detail, as might have been expected—differences both in sediment and in fossils. In all cases, however, where the order of superposition of the layers could be clearly observed, the succession of the various groups of fossils was proved to be essentially the same as in western Europe. Rocks containing approximately the same fossils in widely separated regions may not have been contemporaneous in formation; judging by the

R247

distribution of life in the sea at the present day, they were probably not strictly contemporaneous. Always, however, when sections of the rocks can be studied, the various fossil-bearing deposits are found to be in the same order. The only apparent exceptions to this rule are comparatively local and in regions which show some signs of disturbance. Among the folded rocks of mountain regions, for example, the layers are sometimes overturned; while in districts where soft deposits have been squeezed by the passage of ice over them, they are sometimes broken up into patches which may be pushed together into heaps, not always in the original order.

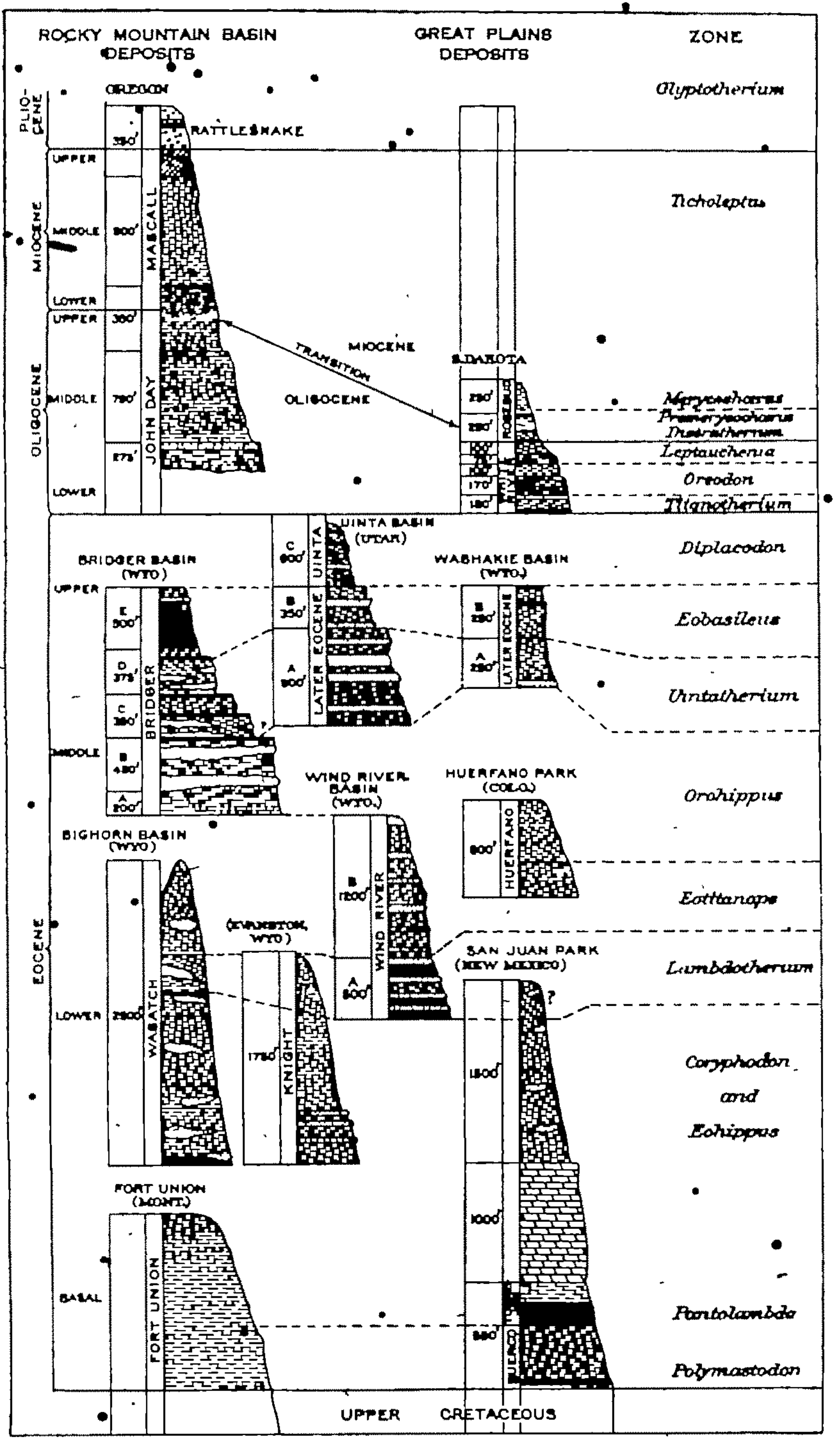

FIG. 1.—A series of sections of the Tertiary land and freshwater deposits containing fossil mammals in western North America, showing how one section can be correlated with another by noting the successive specially characteristic genera which are enumerated in the column to the right. After Henry Fairfield Osborn (*Bull. U.S. Geol. Survey*, No. 361, 1909).

The softness or hardness of a deposit is no criterion of its geological age, but depends merely on local circumstances. For example, on the coast of the Baltic Sea near Reval there is a soft clay which looks like a modern deposit; but it contains some of the oldest fossils characteristic of the Cambrian period, and it is shown in some places to be overlain by fossil-bearing limestones which prove that it is really of Cambrian age. Again, in Canton Glarus, Switzerland, there are hard slates of ancient aspect which are shown by their position to be of Tertiary age, and their contained fossil fishes much resemble those of which fragments occur in the Lower Tertiary clays and sands of south-eastern England. There can be no doubt that these two very different series of rocks are at least in part contemporaneous.

There must naturally be numerous gaps in the series of sea-deposited rocks in every part of a continental area, representing periods when the region was dry land or perhaps covered by water in which there was no sediment. Sometimes the elevation or depression of the land occurs without any tilting, and then, unless an old land-surface is marked by remains of vegetation (as in coal seams and in the fossil forest of the Isle of Purbeck and Portland), it can only be recognised by studying the fossils in the rocks above and below. In Morayshire, Scotland, for example, there is a thick regular series of sandstones, the lowest containing Devonian fishes, the uppermost Permian or Triassic reptiles, with no indication of the long coal period which rocks farther south prove to have intervened between the time of deposition of these two directly superposed sandstones. It is only after long and wide experience of the succession of the rocks in different parts that such "deceptive conformities" can be detected.

It must, indeed, be repeated and emphasised that the whole succession of the marine fossil-bearing rocks in western Europe—the most favourable region in the world—had been clearly ascertained before the idea of organic evolution was accepted by geologists. Fossils were appropriately termed "medals of creation" and were merely used as time-markers in cases where the superposition of the layers was obscured. In spite of earlier discussions, it was only after the publication of Darwin's epoch-making work in 1859 that the meaning of the order in which fossils were known to occur became evident. Group after group was studied from the new point of view, and the study is still in progress. The result is complete confidence in the "evolutionary stages" of all groups of organisms as guides to the relative geological age of rocks which contain them in any part of the world.

This result is important because a large proportion of the land and freshwater deposits of the latest or Tertiary epoch are comparatively limited in extent and thickness, and completely isolated on continental areas which have scarcely been affected by movements since they accumulated. These contain the remains of the ordinary land mammals from their beginning until the present day; and the mammals exhibit the most striking evidence of descent from a common ancestry of any forms of life. At first, especially in North America, it is perhaps true that confidence in the general principles of evolution led to some reasoning in a circle. When collections were made in the territories of hostile Indians there was not much opportunity for detailed field observations. In later years, however, circumstances have improved and experience has been gained, and not only in North America but also in other countries fossil mammals have been collected from beds which have been definitely observed to repose one on another.

Furthermore, there has been much certain correlation by the deposits of one isolated area, as shown by the fossils, overlapping in time the deposits of another isolated area. In illustration of this, Prof. Osborn has published the accompanying diagram (Fig. 1), which explains itself. The general evolution of the horses and camels in North America has thus been revealed, not by assuming the relative age of the beds of different areas in which their fossil remains occur, but by actual correlations made by geologists in the field. Similarly, the relative ages of the primitive ancestors of the elephants in Egypt have been ascertained by examination of perfectly clear geological sections. So many observations of this kind have now been made in various parts of the world, that palæontologists have no longer any hesitation in determining the age of an isolated Tertiary deposit by the state of evolution of the fossil mammals which it contains. They are perfectly justified in doing so, in view of the definite geological evidence which is forthcoming in so great a multitude of cases.

The evolution of life as revealed by fossils is not, therefore, a phantom arising from excess of zeal in pursuing a fascinating idea. It is as strictly the outcome of purely inductive science as any other great generalisation.

Obituary.

MR. W. P. HIERN, F.R.S.

WILLIAM PHILIP HIERN, whose death took place at the Castle, Barnstaple, on November 29, was best known for his work on systematic botany. The son of J. G. Hiern, he was born at Stafford on January 19, 1839, and entered St. John's College, Cambridge, in 1857, where he graduated B.A. as ninth wrangler in 1861, proceeded to M.A. in 1864, and was a fellow of his college from 1865 until 1868. In 1868 he incorporated as M.A. at Christ Church, Oxford, about which time he became interested in botany, and in 1873 published in the *Transactions of the Cambridge Philosophical Society* a monograph of the Ebenaceæ. He then went to the Royal Botanic Gardens, Kew, where he worked out the Meliaceæ and Sapindaceæ for Hooker's "Flora of British India," and was responsible for the greater part of volume 3 of the "Flora of Tropical Africa" in 1877, the Umbelliferæ, Araliaceæ, Rubiaceæ, Valerianaceæ and Ebenaceæ of which he worked out alone, and the Compositæ with Prof. D. Oliver.

A law suit, which had been commenced in 1873 by the King of Portugal against the executors of Dr. Friedrich Welwitsch, who had made botanical collections in Angola on behalf of the Portuguese Government, terminated in a compromise in 1875, and Hiern was appointed by the Court to separate a set and to copy the field notes on behalf of the British Museum. This he proceeded to do, and between 1896 and 1900 published in four parts a "Catalogue of the African Plants collected by Dr. Friedrich Welwitsch in 1853–1861." This completed the account of the dicotyledons, and the remainder of the catalogue was published by members of the British Museum staff. In the *Journal of Botany* for 1895, pp. 139-141, he published a note on the "Plants of Welwitsch's Apontamentos." In conjunction with C. Ficalho he worked out a collection of African plants on which a report, entitled "On Central African Plants collected by Major Serpa Pinto," was published in the *Transactions of the Linnean Society* in 1881.

Having completed his work on the Welwitsch collection, Hiern again went to Kew, where he elaborated the account of the Scrophulariaceæ of South Africa, which in 1904 occupied pp. 121-420 of volume 4, part 2, of the "Flora Capensis," after which he found himself unable to undertake further work on African botany, which was offered to him at Kew. He then retired to Barnstaple and kept the botanical records for Devon, and published in the Botanical Exchange Club Report, 1918, p. 414, a "Clavis to Devonian Sedges," based on the structure of the stems and leaves. During this period he devoted his attention to public affairs and became a Justice of the Peace and County Alderman for Devon.

Mr. Hiern was elected a fellow of the Royal Society in 1903 and of the Linnean Society in 1873; he was also a corresponding member of the Royal Academy of Lisbon. He was a widower, and his only son died some years ago.

C. H. W.

Views and News.

THE annual report of the Development Commissioners which has recently been issued is, as usual, extremely well documented. It contains *inter alia* detailed notes on the work of each of the institutions in receipt of grants for agricultural research and the closely allied " advisory " work. Full details are also furnished regarding the other than purely agricultural agencies, such as the Fishery Department, Rural Economy (as represented by the Rural Industries Bureau), and the Construction and Improvement of Harbours. The introductory portion of the report is devoted to a discussion of the question how far the expenditure by the State of a sum approaching half a million sterling annually is justified by the material progress made in the arts of husbandry. While it is true that " agriculture now requires as much aid as can be got by it from modern science," it is perhaps disappointing to observe that the Commissioners do not stress what, for want of a better epithet, may be termed the spiritual value to agriculture of education and research. If one reflects that the industry is predominatingly one which is dominated by tradition, it is surely no mean feat to have made some progress—to which the labours of the Commissioners have largely contributed—in convincing the agriculturist that the scientific method and the scientific spirit stand for progress, and that all knowledge is not crystallised in the experience of our forerunners. There is little need to deplore the " slow result being secured in the improvement of agriculture " if the Commissioners are satisfied that, with the aid of the advances made by them, new scientific discoveries —new knowledge of truth—have been achieved.

THE Commissioners are on surer ground when they say that " although the present system of agricultural education represents the growth of 35 years, it is only within the past ten or fifteen years that competent instructors [*Sc.* in the scientific principles of husbandry] have been available." It may, in fact, be counted as one of the most notable achievements of the Commissioners that they have promoted measures which by means of scholarships and otherwise have tended to recruit more competent workers to the field of the developments in which they are interested. The report closes with a statement of the finances of the Development Fund, showing that on April 1, 1924, the balance at credit was 320,000*l*. Receipts during the year amounted to 218,000*l*. Payments totalled 314,000*l*, leaving a balance at the end of the year of 224,000*l*. The payments include one of 78,000*l*. to the Irish Free State, presumably in final settlement of its " moral and material " claims against the Fund. In addition, the accounts of the Special Fund (representing the moneys secured under the Corn Production Act) show an expenditure of 152,000*l*. and a balance of 537,000*l*. The Commissioners do not say whether, as may be hoped, their balances are sacrosanct to the Chancellor of the Exchequer.

IT is announced by the Smithsonian Institution that from January 1, 1926, the Institution will furnish gratis to certain American organisations, daily or ten-day mean values of the " solar-constant " of radiation as early and as frequently as results are available from the field stations in Chile and California. In general, results are available about 24 hours after the field observations. The Institution declines, however, to furnish data of this kind regularly to individuals. From the circular in which this announcement is made, we learn that the Smithsonian Institution is concentrating attention on the measurement of radiation. The close study of the relation between radiation and weather is to cease on account of lack of funds. The yearly cost of Mr. Clayton's researches has been approximately 7500 dollars. The generosity of Mr. J. A. Roebling has permitted the Smithsonian Institution to carry them on for the past two and a half years, but that support will cease at the end of this year. Even those who are most sceptical as to the immediate value of the attempt to utilise day-to-day observations of the "solar-constant" in weather forecasting will regret that the work organised by Mr. Clayton is to lapse at the very time when his success is being proclaimed so widely by the Institution.

THE radiation observations of the Smithsonian Institution are made at observatories on mountain tops in desert regions, such sites being chosen so as to give clear dry air and freedom from cloud. The observers are exiled for long periods, to live under conditions that must be anything but pleasant, with little company and none of the recreations of the garden or the field. There is one station at Mt. Montezuma, in the Chilean Andes; the other has just been removed from Harqua Hala, Arizona, to Table Mountain, California. The National Geographic Society has now given 55,000 dollars for the establishment of a third; Dr. C. G. Abbot's recent visit to Great Britain was at the beginning of a tour in which he hopes to select a site in Morocco, Beluchistan, or Tanganyika. It is rightly felt that the establishment of a station in the eastern hemisphere is essential if there are rapid day-by-day fluctuations in the solar heat stream to be investigated Even for the determination of slower variations, the elimination of atmospheric effects peculiar to different parts of the globe is necessary. It is therefore welcome news that this extension of the observing system is being made.

THE Société d'Encouragement pour l'Industrie nationale of France, in view of the important advances which have been made in the last ten years in establishing meteorology on a firm scientific foundation, and of the importance of the subject as one on which the national wealth depends, organised in May last a series of seven public lectures on its recent progress and on its applications These lectures were delivered by some of the most distinguished of the meteorologists of France, and are reproduced in full as the July-August-September issue of the *Bulletin* of the Society. They occupy 120 pages, and are followed by a list of recent French books on the subject, with a page or two of description of the method of treatment adopted in the more important. The lectures deal with the general facts of meteorology, forecasting with special reference to the methods adopted in France and in Norway, applications in aeronautics, wireless telegraphy, navigation, agriculture, and medicine, and with the proper organisation of a national forecasting service.

THE Duddell Medal of the Physical Society of London has this year been awarded to Mr. Albert Campbell, formerly of the National Physical Laboratory. The medal is awarded to those who have advanced the science of physical measurements by inventing instruments or parts of instruments of novel design. Mr. Campbell has won distinction for many new devices connected with the measurement of capacity and inductance. He was one of the first to introduce coils of small self capacity now so largely used in wireless; Campbell's system consists of a number of pancake coils separated from one another by small spaces and held rigidly together. Mr. Campbell has invented instruments for the measurement of frequency, others, known as wave sifters, for the elimination of particular frequencies, instruments, called microphone hummers, for the production of small alternating currents, and vibration galvanometers for use in measurements employing alternating current. The instrument for which he is best known is the standard mutual inductance which forms the basis of most of the accurate measurements of inductance in Great Britain. Mr. Campbell is well known for his skill as an experimenter and has made two determinations of the ohm in absolute units.

FOR some years the Canadian Government has been paying increasing attention to the economic potentialities of the Arctic archipelago. The dispatch of exploring expeditions and the establishment of police posts in the far north are evidence of this new interest. A special publication of the North-West Territories branch of the Department of the Interior entitled *Canada's Arctic Islands* gives an account by Mr. J. D. Craig of the work of the expedition of 1922. The scientific interests of the pamphlet lie mainly in the remarks concerning aviation in the Arctic. Major R. A. Logan, of the Canadian Air Force, who accompanied the expedition, believes that there are many places in the archipelago suitable for aerodromes, thus obviating the necessity of using hydroplanes, which are a danger because of the fragments of ice, frequently almost invisible from a height, that often occur in apparently open water. He thinks that the end of May, June, July, and part of August are almost ideal for navigation on account of weather and continuous daylight, and recommends the use of aeroplanes for survey and patrol work. Major Logan advocates the establishment of an experimental air station, with two small machines, at the police post at Pond's Inlet in northern Baffin Land. This would give valuable experience on which to base more extensive work.

A CORRESPONDENT refers to the difficulty he experiences in preventing fracture of the tinted glass in the sun-cap of his telescope when used for solar observations. The heat absorption of the neutral tinted glass frequently used for this purpose is about three times that of the glasses of which the lenses are made. The tinted glass thus experiences considerable heating effect and, as it possesses no compensating advantage in regard to thermal expansion, there is consequently increased liability to fracture. When a solar prism is used, only about 5 per cent of the heat incident on the prism is reflected into the eye-lens, and in the polarising eyepiece the heat is largely absorbed by the four reflecting surfaces. If neither of these devices is used, it is necessary to limit the amount of heat transmitted by cutting down the aperture of the object-glass to about 2 in. Precautions should also be taken to minimise the stresses set up in the tinted glass on being heated. The glass disc should not be a tight fit in the cell, nor should it be tightly screwed or bezelled in. The thinner the disc is the more readily will equalisation of temperature throughout the glass be obtained. If a thin disc does not provide sufficient absorption, it is advisable to use two such discs rather than a thick one. As a further aid towards securing equalisation of temperature, the disc should not be larger than is necessary to cover the required field. It is possible that, for solar observations, platinised glass discs might advantageously be used in place of tinted glasses. The film of platinum would act as a conducting layer and thus prevent excessive local heating. If necessary, the discs could be made of heat-resisting glass or even of quartz. These platinised glasses have the additional advantage that the absorption produced is almost uniform over the whole visible spectrum, which is not always the case with tinted glasses.

THE photo-electric cell is being studied by engineers as well as by scientific men all over the world. In the newest developments of the methods of sending pictures by wires or through space by radio waves, this cell is an essential device. There are many other applications of it. In *Popular Radio* for November an apparatus is described for sorting out cigars according to colour by means of it. A beam of light is reflected from the cigar into a photo-electric cell. The alteration in the electric current actuates a relay operating mechanism which separates the cigars into three groups, light, dark, and red, according to their shade of colour. The device that has been used to measure the light coming from stars or the light needed by plants is now rapidly being applied to all kinds of commercial uses. In particular, it has recently been found most useful for measuring the intensity and quality of the light emitted from luminous sources, and much research is being carried out in this direction. The "phototron," which is a type of photo-electric cell largely used in the United States, is in appearance like an ordinary radio valve and is mounted on the standard radio valve base. It consists of a plate on which a coating of active alkali metal, generally potassium, is placed. In front of the plate there is a wire grid which serves to collect the electrons. Two of the wires connect to the grid and the third to the plate. The whole is enclosed in a glass bulb which is exhausted of air. When light strikes the plate of potassium electrons fly off. The number of these free electrons is roughly proportional to the intensity of the light. The grid being maintained at a high positive potential relative to the plate attracts the electrons to itself and they can be returned to the plate through a galvanometer. The photo-electric current through the galvanometer measures the number of the electrons. For certain purposes the photo-electric cell may serve as a "radio eye," and the human eye itself may possibly be a living photo-electric cell.

We learn that Max Møller, of the University of Copenhagen, Denmark, has taken up the post of visiting professor of chemistry at the Chulalongkorn University, Bangkok, Siam, under the auspices of the Rockefeller Foundation of New York.

We learn from *Science* that Dr. John J. Abel, professor of pharmacology at the Johns Hopkins Medical School, will receive the first 2500 dollars annual award of the Research Corporation of New York, as an investigator who has made "outstanding contributions to the cause of science without profit to himself."

We understand that, having completed his work on the Atlantic eel, Dr. Johs. Schmidt, Director of the Carlsberg Laboratory, Copenhagen, is now taking up the study of the eels of the Indo-Pacific area. He is leaving in the course of a few days on an expedition to the Pacific to collect specimens and make observations, and expects to be absent for about six months.

Prof. J. W. McBain, Leverhulme professor of physical chemistry in the University of Bristol, will deliver a course of lectures on colloid chemistry at the University of California, Berkeley, Cal., during the first part of 1926, and he will be the guest of honour at the National Colloid Symposium to be held in June at Cambridge, Mass.

Prof. Paul Sabatier, professor of chemistry in the University of Toulouse, and Prof. E. L. Bouvier, professor of zoology (entomology) in the National Museum of Natural History, Paris, have been elected associates of the division of sciences of the Royal Academy of Sciences, Letters and Art of Belgium; Prof. Marc de Sélys Longchamps, of the University of Brussels, has been elected a corresponding member of the Academy.

A. Shimomura has published in the Memoirs of the College of Science, Kyoto Imperial University, Series A, vol. 8, No. 6 (August 1925), an account of the low temperature carbonisation in Fischer's aluminium retort of sixteen coals of oriental origin. The samples ranged from bituminous coals, with more than 40 per cent. of volatile matter, to anthracites. From analyses of the coal and the yields of the various products, it is clear that there are some excellent fuels available in the East.

In pursuance of the policy of carrying out a physical and chemical survey of the national coal resources of Great Britain, which is one of the main aspects of the fuel research work of the Department of Scientific and Industrial Research, a committee has been appointed to deal with the physical and chemical survey of the coalfields of Scotland. The committee includes representatives of the coal owners of Scotland, the Mining Institute of Scotland, the Scottish branch of the Geological Survey, and the Fuel Research Board. Similar committees have already been established in the Lancashire and Cheshire, South Yorkshire, and North Staffordshire areas in England.

The issue of the latest annual report of the Technological Museum of Sydney, N.S.W., in the form of type-written sheets, indicates financial stringency, and this is also evident in the body of the report. None the less, much good work appears to be in progress, and it is particularly pleasing to find recorded a general increase in the number of applications for material for school museums. The museum has not only supplied exhibits to the schools, but has also encouraged teachers to interest their pupils in collecting local specimens and in sending them to be named and classified. This serves a double purpose: the pupils' knowledge of botany, geology, and local products is increased, while the school museums are built up by their efforts, and a keener interest created.

An address delivered at a birth control conference in New York last March by Dr. Louis Dublin, Statistician to the Metropolitan Life Insurance Co., New York, which appears in *The World's Health*, vol. 6, No. 12, p. 505, is of some interest in connexion with the recent correspondence on the subject in Nature. Dr. Dublin is an opponent of the broadcasting of contraceptive information without reserve, on the grounds that propaganda have been elaborated prematurely (1) without due regard to the permanent interest of the State, (2) without adequate consideration of the real population tendencies which to-day prevail, and (3) without sufficient regard to the trustworthiness and safety of the procedures recommended and to the consequences on the spiritual life of those who are influenced by the advice tendered.

The University of Masaryk, at Brno (Brünn), issues a number of separate papers describing work carried out at the University under the general title "Publications de la Faculté des Sciences." Several botanical communications in this form have recently been received. These include systematic works, such as a revision of the genus Onobrychis (in Latin), by G. Širjaev, an account of the Compositæ collected in Turkey and Persia, by Dr. Fr. Nábělek (also in Latin), a phytogeographical study of the distribution of lichens in Moravia by Jindřich Suza (in Czech with an English summary); and two publications from the Laboratory of Plant Physiology, namely, (1) on growth reactions produced by change of pH on roots of *Pharbitis hispida* Choisy (in English), by Ferd. Herčík, and (2) on the growth of structures formed by boundary reactions between solutions of electrolytes in gelatin and in water, by Vladimír Morávek (in Czech with English summary).

In the case of the Mollusca, almost more than in that of any other group of the Invertebrata, are figures necessary accompaniments to descriptions of new species, owing to the extreme difficulty of defining satisfactorily their appearance by words alone. Some societies, like the Malacological Society of London, make a practice of giving figures with all new descriptions, but that wise course is far from being so universal as it should be, while in the past it has been neglected to a lamentable degree. Conchologists, therefore, owe a great debt to the veteran Dr. W. H Dall for his "Illustrations of unfigured Types of Shells in the Collection of the United States National Museum" (*Proc. U S. Nat Mus*, 66, Art. 17), to which have been added a few figures of species elsewhere inadequately illustrated or depicted in publications difficult of access, as well as descriptions and figures of 17 new species The work comprises 36 plates giving figures of some 200 species, and 41 pages of text confined mostly to references to the original descriptions. The figures, which were drawn as opportunity offered and put aside until publication could be made, are in different styles and reproduced by several different processes, and are all very good and clear despite the sacrifice of pleasing uniformity.

THE sixth of the booklets, 14 cm. × 11 cm., issued by the Cambridge Instrument Company, describing the firm's productions, contains 64 pages, and is devoted to instruments which have been at various times designed for special purposes. In each case a photograph of the instrument described is given, and as a rule its over-all dimensions are recorded. The first portion of the booklet is devoted to magnetographs of various types, to Galitzin seismographs, and to tide recorders. Then follow spectrographs ranging from the infra-red to the ultra-violet, astronomical and sunshine recorders, X-ray track apparatus, comparators for the accurate measurement of standard tapes for geodetic surveys, deflexion and crack meters for investigating the strains in structures, permeameters for measuring the flow of gases through fabrics, sound-ranging apparatus as used in the War, and pressure recorders for use in coal-dust explosion tests. Brief notes are supplied as to the capabilities of each instrument, but more detailed descriptions are available, on request, for the use of those who require further information.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A professor of biology and a professor of bio-chemistry in the College of Medicine, Singapore—Private Secretary (Appointments), Colonial Office, 38 Old Queen Street, S W.1 (January 9). A research chemist, with knowledge of the clay industries, and research experience in connexion with clay and clay products, at the Building Research Station, Garston, Watford, of the Department of Scientific and Industrial Research—Secretary, Department of Scientific and Industrial Research, 16 Old Queen Street, S W.1 (January 11). Head of the Engineering Department at the L.C C. Hackney Institute, Dalston Lane—Education Officer (T (1) (a)), The County Hall, Westminster Bridge, S E.1 (January 18) An assistant lecturer in Economics at University College, Southampton—Registrar.

Our Astronomical Column.

SUNSPOT DATA FROM CHINA.—Solar observations have been carried out systematically and with great zeal for many years at the Zô-Sè Observatory, China, under the direction of Father Chevalier of the Jesuit Mission at Shanghai. Vol 14, No 1 of the *Annals* of this observatory contains lists of sunspots and of prominences observed during the three years 1920, 1921, and 1922 The heliographic co-ordinates of the spots, date and hour of meridian passage, observed areas, and other data are carefully recorded, and in the case of the prominences the latitudes, heights, areas, and relative brightness are tabulated Apparently the opportunities for successful observation of prominences are limited to about sixty days annually, but these observations will nevertheless be of considerable value in co-operation with visual observations made elsewhere.

In discussing the results of the sunspot data, Father Chevalier concludes that spots do not appear at random in different regions of the sun's surface, but tend to develop in certain areas over considerable periods of time When the observations of latitude and longitude are plotted over long periods of time, there is thus a tendency to form groups, and these sometimes tend to be drawn out obliquely with reference to the meridians, as though the foci of activity moved slowly in longitude towards east or towards west

The remarkable interchange of activity between the northern and southern hemispheres, and the varying positions of the equatorial zone of minimum activity, are also brought out in these studies.

THE PHYSICAL NATURE OF THE SOLAR CORONA —The *Zeitschrift fur Physik* of October 20 contains the second part of a paper on the above subject by Dr. W Anderson, with a discussion of the photoelectric and the electromagnetic theories of the corona, both of which he shows lead to great difficulties The observations of H. Ludendorff during the solar eclipse of September 10, 1923, are referred to; they show that the maximum of intensity in the spectrum of the corona coincides exactly with that in the spectrum of the photosphere, which is contrary to results previously obtained, and shows that the corona does not consist of incandescent particles, since the temperature of such particles would certainly be lower than that of the photosphere, and the intensity maximum would be shifted towards the red. Dr Anderson proceeds to obtain an estimate of the effective molecular weight of the corona, based on the fact that since the pressure is small the mass absorption coefficient and the temperature radiation are small, so that alterations in state must be adiabatic. He estimates the temperature in the lower layers as 4824° Abs., which leads to a maximum value of the effective molecular weight, m, of 1/1733·5 and a minimum of 1/1906·8, in the highest regions the temperature estimate is 4236° Abs. and m lies between 1/1787·7 and 1/1985·1, with similar values for intermediate heights. According to L Flamm, the "atomic weight" of "electron gas" is 1/1832·8, which lies between these maxima and minima.

Research Items.

Some Hindu Observances.—In the *Scientific Monthly* for December, Dr. Elsie Clews Parsons records autobiographical reminiscences of Somesh Chandra Bose, a Bengali of the Kshattriya caste. His family are Kulin Kasyathas and his wife was Bal, a division of the Kasyathas for whom it was an honour to intermarry with the Boses, their superiors. His own immediate family was exceptional, in that its head, an "uncle," was seventy-five years old and had not followed the usual custom of men of his age and resigned his authority to a younger brother or a son. All the names of the family had been given by this uncle instead of, as usual, suggestions having been offered by several of the family at the rice-giving ceremony. The rite of "beginning education" was performed at the age of five years by the family Brahmin, who put the pen in the child's hand and guided him in forming the letters. Although S C Bose was at first slow to learn, he developed a prodigious memory and an extraordinary mathematical capacity In speaking of marriage he says that parents pay a good deal of attention to colour. They know that it is inherited, particularly if it is dark. The standards of beauty are figure, contour of face and colour. Parents may be put to a good deal of expense if a daughter is dark—an interesting commentary in practice on the colour theory of caste

Oyster Breeding Experiments.—Experiments to ascertain the conditions governing the production and settlement of oyster spat have been carried on since 1918 at the Ministry of Agriculture and Fisheries' Shellfish Research Station at Conway, and this year the Ministry's mussel purification tanks at Lympstone were also used for this purpose during the off-season for mussel cleansing. A feeding experiment with ordinary yeast carried on this year met with some success The young oysters were able to swallow the yeast cells, and in one tank so treated at Conway a useful spatfall was secured. At Lympstone a very heavy spatfall was obtained; so many as 150 oysters setting on a tile. Two special features were noted in connexion with the tank where the heaviest spatfall occurred: first, that there was a very large population of small fish (gobies) which were absent from other tanks; and secondly, the presence of a minute vegetable organism. The intestines of the oysters were found to be full of this green material, almost to the exclusion of other organisms. The gobies may have kept the water clear of certain organisms which compete with the young oysters for food. Some hundreds have therefore been transferred to one of the tanks at Conway, and it is hoped that they may breed sufficiently to allow of experiments being carried out next year Cultures of the special vegetable material on which the oysters were observed to feed have been made, and further experiments with this organism will also be carried on next season. Another feature was the rapid growth of the Lympstone oysters, which reached a diameter of 2 inches in less than two months: a rate of growth outside all previous experience The spat has been laid down in the Exe Estuary, and in the Menai Straits; the mortality has been negligible Some of the spat has also been laid down by a large firm of oyster planters at Brightlingsea.

Waxes of Indian Cottons.—A curious fact emerges as the result of a study by Leslie V Lecomber and Maurice E Probert of the waxes of cotton samples from different countries, by the methods which have recently been worked out in the laboratories of the British Cotton Industry Research Association (*Journal of Text Inst*, vol. 16, No. 11, November 1925). Whilst American and Egyptian cottons show no constant differences in the composition and properties of the wax extracted by carbon tetrachloride, which could be regarded as characterising the country of origin, in every case waxes from Indian cottons prove to be characterised by a high saponification value. This is the most outstanding character of the Indian waxes, but they also possess a relatively low melting-point, high acid and iodine values, and contain a low percentage of unsaponifiable material.

Grass Rusts of South America.—J. C. Arthur reports upon the collection of grass rusts made by the late Prof. Holway during extensive journeys in South America during 1919–22, journeys made especially with the view of collecting rust fungi on grasses and on alternative host plants, in the *Proceedings of the American Philosophical Society*, Vol 64, No 2, 1925. This collection forms the basis for a general re-examination of all recorded data as to grass rusts in S. America, with the result that 74 species are listed with notes as to host plants and distribution; five-sixths of these species were represented in the Holway collections

"Mouldy Rot" in Hevea Brasiliensis.—A paper by F. W South and A. Sharples on the spread of this disease in Malaya is of interest as the record of the spread of a fungus parasite, presumably introduced about 1916 in some plantation through plant materials imported into the country, until it is now well established in a large part of the rubber-growing area (Bulletin No. 37 of Dept of Agriculture, Straits Settlements and Federated Malay States). Inoculation experiments seem to establish definitely the identity of the causal fungus as *Sphæronema fimbriatum* (E. and H). One spore form of this fungus, a dark-coloured endospore or macrospore, is very resistant to drying, and as the fungus is a wound parasite, it may spread by this means on the knives of the tappers as they pass from one plantation to another. The disease has now a firm hold and there seems little likelihood of its eradication, but the authors describe experiments, confirmed by extensive trials on a commercial scale, which show that it may be kept under control by painting or spraying antiseptics on to the tapping surface. Particularly good results seem to have been obtained with a proprietary article known as "Agrisol."

Zoological Position of the Arthrodira.—The position of the Arthrodira and Coccosteomorphi among fishes has for long been debated. At one time they were thought to belong to the Dipnoi, but more modern views have brought about their removal from that group without, however, assigning them to any other definite place. Dr. Eric Stensio of Stockholm has just published a most interesting and important paper dealing with the question in vol. 4, No. 4, of the Geological Series of the Field Museum of Natural History (Chicago, October 1925). It appears that a specimen of Macropetalichthys in the collections of the Museum gave promise of showing, after suitable development in the laboratory, something of the structure of the primitive cartilaginous neurocranium It showed eventually much more than this, in that it has enabled Dr. Stensio to describe in detail much of the anatomy of the brain, nerves and course of the blood vessels. These are fully described and figured in the first part of his paper. The author then describes a new genus, *Epipetalichthys wildungensis*, and in a third section gives a general review of the whole group. It comes rather as a surprise to find a list of eleven characters in the primordial neurocranium which are essentially elasmobranch, and in his concluding remarks the author, after pointing out that the Arthrodira are certainly not Crossopterygians, nor Dipnoi, nor Palæoniscids, nor *a fortiori* Actinopterygians, comes to the conclusion that as they are undoubted fishes unrelated to the non-fish Ostracodermi, then they must be elasmobranch in affinities. This view has much to commend it, but necessitates a somewhat drastic re-orientation of our ideas as to the course of evolution in the cartilaginous fishes, in that they must now be considered to have come from ancestors with a covering of true dermal bones which they have secondarily lost. The fact that bone is an exceedingly primitive substance, *e g.* in the ostracoderms, gives some support to the thesis

SOLUTION LAKES IN SWITZERLAND.—In a paper read on December 7 to the Royal Geographical Society on the lakes of Scotland and Switzerland, Prof L. W. Collet directed attention to the numerous basins produced by the solvent action of water on calcareous and dolomitic strata in Switzerland. These lakes are of two kinds, according to whether they occupy a doline or a polye, the latter being the larger, and due to the union of several dolines. Lakes of this nature in the Alps frequently have their floors covered with deposits of impervious material derived from ground moraines of ancient glaciers. This points to the basins not being entirely due to chemical action In fact, Prof. Collet believes that in the majority of cases glacial action has played a part in the process of deepening The glacier has cleaned out and deepened a cavity formed by chemical action, and its ground moraine has completely closed up the fissures in the limestone; thus the existence of a lake has become possible. Thus the lake of Mutten, which was generally considered to be a corrie lake, proves on close examination to be a solution basin with moraine matter on its floor. The Oberstockensee and the Daubensee are cited as other examples of solution basins

PLEISTOCENE CAVE FAUNA OF MALTA.—The annual report of the Valletta Museum for 1924–25 records many interesting additions made by Miss G Caton Thompson to the fauna of Ghar Dalam. The bones were determined in the Geological Department of the British Museum by Miss D. M A. Bate The following represent genera not hitherto recorded from the cave deposits of the Maltese islands: a shrew, *Crocidura*, cf. *leucodon*; a bat, *Rhinolophus*, cf *euryale*, a field mouse, *Apodemus sylvaticus* The following species, recorded from these deposits for the first time, are now, except the owl, either rare visitors or entirely absent from the region: the short-eared owl, *Asio accipitrinus*; the sheldrake, *Tadorna cornuta*; the rook, *Corvus frugilegus*; and, most noteworthy, the carrion crow, *Corvus corone*. Other new records are the thrush, the blackbird, a very small fox, a small carnivore (? wolf). Considering the amount of work previously done at Ghar Dalam, this is a remarkable harvest for one season, and shows the advantage of expert co-operation. The importance of such precise details in working out the geography and climate of the period needs no emphasis.

PORCELAIN CENTRIFUGAL VESSELS IN CHEMICAL ANALYSIS.—In the *Chemiker Zeitung* of November 20 there is an interesting account by Pincussen and Arnstein of the adaptation of the centrifugal method of filtration to chemical analysis in physiological chemical analyses. The rapidity, ease, and cleanliness with which separations can be obtained render this method superior to the older methods of filtration in physiological investigations, since changes which are due to adsorption phenomena can be avoided with much greater certainty. The new vessels are made of porcelain and can therefore be ignited and weighed if necessary. Tests were made of the efficiency of the method by carrying out estimations of sulphuric acid as barium sulphate and of aluminium as alumina. In both cases the error was greater than that obtained in the usual way. On the other hand, the quantities of material weighed were unusually small.

THE ABSORPTION OF HYDROGEN BY PALLADIUM AND BY PALLADIUM SILVER ALLOYS.—The great difference between the atomic weights of palladium and hydrogen makes it impossible to determine directly the position of the hydrogen atoms with respect to those of palladium by means of X-ray spectrograms If, however, the density of saturated palladium, which at 0° C and 760 mm. Hg. absorbs 523 times its volume of hydrogen, or about one hydrogen to two palladium atoms, is calculated on the assumption that the hydrogen atoms replace those of palladium in the lattice, the value obtained is 7·3, while that observed is 10·76. Messrs. F. Kruger and A Sacklowski, in a paper in the *Annalen der Physik* for November, conclude that the hydrogen atoms are distributed between the atoms of the palladium lattice, which is thus expanded considerably. They have investigated electrolytically the absorption of hydrogen and determined the dimensions of the resulting lattices for a number of alloys of palladium and silver. The result is rather remarkable, the lattice dimensions of the hydrogen-free alloys increase according to a linear law as the amount of silver increases, in accordance with Vegard's law, those of the hydrogen-saturated alloys remain practically constant from pure palladium up to about 70 per cent silver, the amount of hydrogen absorbed following a linear law as the amount of silver is increased, and dropping to zero for about 70 per cent of silver in the alloy.

THE PHOTOGRAPHIC ACTION OF H-RAYS FROM PARAFFIN AND ALUMINIUM—The hydrogen nuclei ejected by collisions of α-particles have so far been mainly investigated by the scintillation method and by the Wilson cloud method. Muhlstein in 1922 indicated the possibility of the use of photography for the purpose, and in the *Zeitschrift fur Physik* of October 5, Fraulein M. Blau describes a method, based on that employed by Michl in connexion with α-rays, in which the H-rays produced by the bombardment of a thin sheet of paraffin with α-rays from polonium pass at a rather steep angle through a photographic film, each H-nucleus producing a row of black dots which appear when the plate is developed. Various difficulties had to be overcome owing to the long exposure required, which made it necessary to reduce all photographic action due to β- or γ-rays to a minimum, and it was impossible to obtain results with the longer range α-particles produced by radium C, which give H-rays with a range of nearly 30 cm. and could be expected to give longer rows of black dots than the H-rays due to the α-particles of polonium, the range in air of which is only about 16 cm A comparison experiment in which the paraffin sheet was replaced by a layer of lamp black, containing the same amount of carbon as the paraffin with very little hydrogen, did not show the rows of dots Aluminium foil free from adsorbed gases also gave H-ray tracks in the photographic plate when bombarded with α-rays from polonium, so that it appears that the atoms of this metal can be disintegrated by α-rays of less than 4 cm. range, which agrees with the results of E. A. W. Schmidt, and contradicts those of Rutherford and Chadwick, who found a lower limit of 4 9 cm

The Ignition-point of Gases and its Relation to Volume and Pressure.[1]

AS part of the investigations on the ignition of gases undertaken by the Safety in Mines Research Board, Prof. H. B. Dixon and Mr. J. Harwood have measured the change of volume required to fire various mixtures of methane with air, and of hydrogen with oxygen, when these gas mixtures are suddenly compressed in steel cylinders.

As the compression was carried out originally, according to Prof. Nernst's suggestion, the piston was driven down by a falling weight until it was stopped by the explosion of the gases, the distance within the cylinder traversed by the piston registering the compression. Now the gases do not burst into flame at the moment the ignition-point is reached; an interval of self-heating occurs (varying in length with different gas mixtures) during which the piston will continue to descend—thus indicating a greater compression, and higher temperature, than was really needed to fire the gases. This error was corrected by stopping the piston mechanically by means of a head which was caught by steel collars of the desired thickness placed over the mouth of the cylinder. Later on another source of error was pointed out, namely, the possibility of the self-heating gases pushing up the piston and weight and thus losing heat by doing work at the beginning of the pre-flame period.

Methods have now been adopted which meet these two sources of error. The older apparatus was fitted with three powerful clamps which by means of strong springs should slide over the weight in its lowest position and hold it rigidly down on the piston. In practice it was found that the rebound of the weight when suddenly stopped prevented the certain action of the clamps: but the insertion of a small lead cylinder between the piston head and the weight allowed the weight to continue its fall (after the piston was stopped) for a fraction of a second, during which the clamps had time to make good their hold and keep the weight tight against the flattened-out lead disc.

A new machine has also been designed in which a toggle-joint (as used by Ricardo) is straightened out by a falling weight. This mechanism ensures that the motion of the piston may be stopped at any given point, and also that it may be held firmly in that position if the toggle-joint is kept horizontal. The new machine has a cylinder of twice the diameter of the old, and it is found that, while the rapidly firing mixtures such as electrolytic gas require nearly the same compressions in the two machines, the slower firing mixtures of methane and air show lower ignition-points in the larger cylinder.

To study the effect of differences in initial pressure on the ignition-point of gases—a question raised by the observation of the powerful compression-waves propagated in the firing of the high explosives used in coal-mines—Prof. Dixon, in collaboration with Mr. W. F. Higgins, has modified the concentric tube apparatus, designed some twenty years ago, so as to observe the ignition-point of various gases in air and in oxygen at pressures above and below the atmospheric pressure.

The silica cylinder surrounded by its electric furnace is encased in a strong steel vessel, and is fed from below with compressed air or oxygen—for high-pressure experiments—the excess of air escaping (with the products of combustion) at the top of the vessel. For low pressure trials the air, or oxygen, is allowed to enter below and is drawn off at the top by a motor-driven exhaust-pump, so as to maintain a constant pressure during each experiment. The combustible gas is admitted through the narrow central tube, which opens in the middle of the large cylinder, by turning a tap on the outside of the vessel—the gas passing from the holder through adjustable valves. Observation of the flame is made through a glass window, and the interval between the turning on of the gas and its ignition is timed by means of a pendulum and metronome ticking half-seconds. As the temperature rises, this interval or "lag" becomes shorter in successive experiments, and when it falls to 0·5 sec. (0·6 sec. in the case of methane) the temperature observed is called the rapid ignition-point.

The effect of variations of pressure on methane and on hydrogen was found to be very different. With methane in air, the rapid ignition-points fell regularly as the pressure was increased from 1 to 7 atmospheres, and when the pressure was lowered the ignition-points continued to *rise* so long as the gas would light, although the *rate of rise* fell off as the pressure was reduced from 150 mm. to 100 mm. of mercury. On the other hand, although the ignition-point of hydrogen in air fell regularly as the pressure was increased from 2 to 7 atmospheres, it also fell very sharply as the pressure was reduced from 150 mm. down to 75 mm. of mercury.

The experiments in oxygen confirmed these made in air, except that the rapid ignitions of methane in oxygen showed a maximum temperature at 200 mm. pressure; above or below this pressure, the ignition-point fell. This fall in the ignition-point at very low pressures appears to be a general property of gases: its cause is as yet unexplained.

---

[1] Substance of two papers, (1) "On the Firing of Gases by Compression," by Prof. H. B. Dixon and Mr J Harwood, and (2) "On the Ignition-point of Gases at Different Pressures," by Prof H B Dixon and Mr. W. F. Higgins, read before the Manchester Literary and Philosophical Society on Tuesday, November 10

British Marine Biology.

THE Marine Biological Association has now at Plymouth a laboratory in the same class as those at Naples and Woods Hole. It only lacks that cosmopolitan element, which largely makes the charm at Naples. It has its zoological, physiological, and fisheries departments and a research vessel that can visit even deep-sea areas. Its growth, while largely due to the recognition of the importance of basal scientific research work in the elucidation of practical problems by the Development Commissioners, is chiefly owing to the broadness and scientific insight of its Director, Dr. E. J. Allen, this being the main factor in attracting the fifty-six naturalists who occupied its tables in the past year; Dr. Bidder has also been generous and, as treasurer, active in obtaining money for several new buildings.

The journal of the Association (vol. 13, No. 4), by arrangement, includes the work of other British marine laboratories. Prof. Meek leads off with a critical account of legislation on the catching of crabs and lobsters on the east coast of England. The crab sheds its shell in autumn and takes some months to reform and harden its new coat It is poor in quality then, and the fishing is a most destructive one. To protect it the Eastern, North Eastern, and Northumberland fisheries committees have closed the crab fisheries at different times during these months. The author analyses the results in comparative graphs, which show quite a remarkable benefit in the total catch of each district. Northumberland gives particularly striking results, while it is shown that the Scotch coast to the north has gained by migration about a quarter of a million female crabs each year owing to this closure The paper should be read by every legislator for, if it does nothing else, it shows by inference how foolish and wasteful it is, scientifically speaking, to have fisheries in each of our three islands in the hands of different authorities, and coastal fisheries under a series of independent local committees. Each county might just as well manage the railways within its boundaries.

F. S. Russell deals with the diurnal changes in the distribution of the macroplankton. The place sampled was about half way between the Plymouth breakwater and the Eddystone, in 51 m. of water. The date was the full moon on July 15-16, 1924, fair weather. The author clearly hopes that he was beyond the region of local swirls and upward currents, but to convince us of this he should surely have taken serial temperature and pH readings. We should have liked also to know a little more about the weather and particularly the strength of the light. Five series of observations at different depths were taken with a large round stramin cloth net of 2 m. diameter at approximately equal intervals Each haul was 10 minutes A depth recorder was attached, and the depth path of the net at each haul was recorded The organisms caught were counted, and lists are given of those definitely migrating to the surface at night, of those dispersing evenly through the body of water, of those making smaller but yet definite upward migrations, and lastly of those not affected. The young stages of fish are omitted, but are to be recorded in a separate paper. Of isolated facts, 14,000 Tornaria-larvæ caught in the surface haul at midnight is interesting, while the various crustacean larvæ are particularly well done, thanks perhaps to the stimulus of Dr. Lebour. The work is of real importance and clearly must be repeated , we would like it to be done much farther from land and at a season when larvæ are less abundant, so that the whole problem may, to start with, be simplified as much as possible.

C. F. Hickling has been working on the Atlantic slope and there he obtained luminescence in a species of deep-sea fish, *Malacocephalus lævis*, produced by an epithelial invaginated gland opening around the anal papilla and lying in front in the ventral wall of the abdomen ; it is of considerable size and is provided with connective tissue struts and a muscle sheath. The secretion is highly luminous and appears to be always poured out by the dying fish. It goes into solution in water, but constant shaking (? oxidation) is required to maintain its luminosity. It is not due to bacterial action, but to a definite substance which has been termed luciferin. It is suggested that the material may be shot out as ink is by a cuttle-fish, only here a cloud of light, while the fish darts off to escape from danger ; it is also possible that the light may be used to attract food.

Four papers deal with Crustacea. Miss Jorgensen describes the early stages of Nephrops. Dr. Lebour has nearly completed the description of the stages of Nyctiphanes, while working in general on Euphausidæ, a family of considerable importance as being fed on largely by herring. Her knowledge of and insight into crustacean development is clearly an asset of importance to the Laboratory. Dr. Stephenson adds a new species of anemone to the British fauna, this being only the second new form in more than sixty years, a remarkable tribute to the zeal and insight of Gosse, whose beautiful pictures are so well known. We hope E Mary Stephenson will continue and extend her work on the same group wherein she emphasises the fact that the cinclides may be soft spots " which can rupture neatly and without harm to the animal when needed as safety-valves." We always like to know in such work the preservatives employed, and we think important results in the minute anatomy will be attained by employing the methods of Ramon y Cajal's laboratory.

Of other papers we may refer to C. M. Yonge's account of the pH in the gut of Mollusca, wherein he shows that the origin of the general acidity of the entire gut lies in the style which dissolves rapidly in alkaline media, its maintenance being the result of a balance between the rate of its secretion and its dissolution ; the acidity may also be caused by the salivary and digestive glands. H. W. Harvey's paper on oxidation in sea-water is mainly concerned with the actual processes, the action of a catalyst being inhibited by dissolved organic substance ; the paper suggests further researches that may well lead to economic results Finally, a new technique for studying the dissociation of oxyhæmoglobin, described by Pantin and Hogben, will make a wide appeal as it is suitable for class work. The Journal concludes with abstracts of thirteen memoirs, published elsewhere but describing the work done at the Plymouth Laboratory.

J. Stanley Gardiner.

Motor Fuels.

To the layman the subject of motor fuel is symbolical of the entire petroleum industry, and in view of the fact that this commodity is at least a tangible and universal expression of commercial activity, there is perhaps something to be said for the idea Listeners to the Howard Lectures at the Royal Society of Arts, delivered by Prof. J. S. S. Brame and published recently in the Society's journal, would, however, have arrived at very different conclusions concerning not only the scope of the industry, but also the complex subject of motor fuels considered as a whole, and they would have at least been impressed with one fact, namely, the rapid strides recently made in research whereby supplementary fuels to petrol are gradually being made available for general consumption.

In his first lecture the author dealt with petroleum, cracked spirit, casing-head spirit and motor benzole, and his remarks on cracked spirit were of particular interest, as this is still a much-discussed product, both from technical (*e.g* refinement) and economic (utilisation) aspects. Efficiency of plant, loss of initial material, gas and carbon formation, and the commercial possibilities of treating residue-oil, are some of the many problems raised in this connexion, though it is clear that they are now well on the way to adequate solution. Cracked spirit is generally blended with ordinary petrol much as is the case with casing-head spirit, neither products being suitable for direct use with motor cars. Referring to benzole, the author remarked on the increasing importance of absorption processes for extracting this fuel from coal or coke-oven gas , such processes simulate those employed for recovering petrol from natural gas, *i.e.* casing-head spirit, though in the former case silica gel has apparently been successfully utilised as an absorbent.

In his second lecture, Prof. Brame discussed power alcohol, fire-risks with fuels, physical properties, boiling ranges, explosive ranges, and calorific values of various direct and mixed types. Regarding alcohol, he rightly stressed not so much the value of this compound as a fuel, but the problem of its cheap, commercial production, without which its application is impracticable. The third lecture dealt with fuel-air mixtures, composition of fuels and efficiency, current research in the United States, and the interesting subject of "anti-knock" compounds, including the famous lead tetraethyl—the distinctive but poisonous ingredient of the temporarily prohibited ethyl gasoline in America. The intricate problems of mixed fuels such as petrol-benzole, petrol-tetralin, petrol-alcohol, and alcohol-ether, etc., were touched on, the whole syllabus thus forming a most comprehensive review of the subject up to the present time

---

University and Educational Intelligence.

CAMBRIDGE.—The election of Prof. J. Barcroft to the chair of physiology did not come as a surprise to those who are acquainted with the Cambridge Physiological School He was elected a fellow of King's in 1899, in which year he won the Walsingham medal; he has held several important physiological posts and was appointed reader in 1919.

Dr. R. G. W. Norrish has been elected to a Junior Fellowship at Emmanuel College; he was recently admitted to the degree of Ph.D. for physico-chemical research.

Early in December the town was visited by numerous candidates for entrance scholarships and exhibitions. It is reported that the numbers offering physics and chemistry are considerably greater than usual, whilst those taking biological subjects have fallen off. This is an unfortunate state of affairs in view of the shortage of high-grade biological students.

EDINBURGH.—The University Court has made the following appointments in the Department of Public Health:—Colonel P. S. Lelean, until recently professor of hygiene in the Royal Army Medical College, to the Bruce and John Usher chair of public health, Dr. William Robertson, Medical Officer of Health of the City of Edinburgh, to be Director of Instruction in Sanitary Administration.

Dr. Archibald Milne, Depute Director of Studies in the Edinburgh Provincial Training College, has been appointed a lecturer in the University to conduct the course on school organisation and administration, and Mr. R. B. Kerr, a lecturer in education in the Training College, to be a lecturer in the University to conduct the course on modern educational systems and problems.

LIVERPOOL—At a meeting of the University Council held on December 15, Associate Professor F J. Teago was appointed to the Robert Rankin chair of electrical machinery. Dr. Teago served his apprenticeship in engineering with Messrs. Charles Parsons and Co., returning to the designs staff of this Company in 1909, after spending three years at Armstrong College, Newcastle-upon-Tyne, where he graduated with the degree of B.Sc. In 1912 he was appointed lecturer in electrical engineering at the University of Liverpool. During the War he occupied important positions in connexion with the design of electrical machinery, and as Assistant General Manager of the Ministry of Munitions Steel Works, Manchester. After the War he was appointed senior lecturer in electrical engineering at the University of Liverpool, and in 1924 the title of associate professor was conferred upon him. In 1924 he was admitted to the degree of D.Sc. (Durham). Dr. Teago has published a number of papers on electrical machinery, three of which have been awarded special premiums by the Institute of Electrical Engineers.

LONDON.—Prof A. V. Hill has, on his appointment by the Royal Society to a Foulerton chair, resigned the Jodrell chair of physiology tenable at University College. He will carry out his research work at University College, and the Senate has resolved that he shall continue to hold the title of "Professor of Physiology in the University of London" in respect of the functions to be discharged by him at that College.

The following doctorates have been conferred:—*D.Sc.* (*Embryology*), Mr. A. S. Rau (University College) for a thesis entitled "Contributions to our Knowledge of the Structure of the Placenta of Mustelidæ, Ursidæ and Sciuridæ"; *D.Sc.* (*Physics*), Mr. W. B Haines (University College and the Rothamsted Experimental Station) for a thesis entitled "Studies in the Physical Properties of Soils"; *D Sc.* (*Metallurgy*), Miss Constance F. Elam (Imperial College—Royal School of Mines) for a thesis entitled "(1) Tensile Tests of Crystals of an Aluminium-Zinc Alloy; (2) The Orientations of Crystals in Metal Test-pieces subjected to small Strains followed by Heat-treatment."

THE University College of the South-West of England, formerly known as University College, Exeter, directs attention in its report for 1924–25 to the harmonious development (justifying its change of name) of its scheme for co-operation with the Technical School, Plymouth. With effect from the beginning of the current session, the more technical part of the School of Pharmacy has been transferred to Plymouth, while the pure science part of the curriculum continues to be provided at Exeter as well as at Plymouth. The Department of Law also provides courses at Plymouth, and a project is on foot for establishing a School of Commerce there. The total number of full-time students has increased from 313 to 332, the increase of science degree students alone being from 67 to 87, and of pharmacy diploma students from 10 to 18 The number of degree students has more than doubled in the last four years.

STATISTICS of State Universities and State Colleges for the year 1923–24 are published in Bulletin, 1925, No. 12 of the United States Bureau of Education. Similar annual returns have been published by the Bureau for the past sixteen years, but in this bulletin appears for the first time a tabular statement of tuition and other fixed annual charges payable by students. The subject is one to which much attention has been directed of late. In the institutions, 106 in number, represented in the returns, the total student enrolment, excluding the summer school, was men 148,230, and women 77,567, and the student fees paid, excluding board and room rent, amounted to sixteen million dollars. There is very great diversity of practice in regard to the fixed charges which students are called upon to pay in these state universities and colleges, the amounts varying, in arts and sciences, for tuition and other fixed annual charges, excluding laboratory fees, from nine dollars in the University of Oklahoma to 314 dollars in Cornell University. The table includes figures for medicine, dentistry, law, and pharmacy as well as arts and sciences; in almost all instances the rates for other courses of study such as engineering and agriculture are the same as for arts and sciences. The highest professional school tuition charges are 500 dollars per annum for the Medical School of the University of California. Many institutions at which tuition is nominally free impose "incidental" and "registration" charges, generally small but sometimes considerable, *e.g.* Pennsylvania State College, 100 dollars.

Contemporary Birthdays.

January 1, 1855. Sir Charles L Morgan, Past Pres. Inst.C.E.

January 5, 1846. Sir John Arrow Kempe, K.C.B.

January 8, 1845. Rt Hon. Sir Herbert E. Maxwell, Bart., F.R.S.

January 8, 1856. M le Prof. Henri Lecomte, Natural History Museum, Paris.

January 8, 1868. Sir Frank W. Dyson, F.R.S.

Born at Edinburgh, Sir Herbert Maxwell was educated at Eton and Christ Church, Oxford. As naturalist, antiquary, and worker in the public service, Sir Herbert's many-sided activities have had ample play on both sides of the Border. An ardent chronicler of Scottish history, he was president of the Society of Antiquaries of Scotland, 1900-13, and a lecturer in the University of Glasgow during that period. A recognised authority on Scottish historical monuments, he was Rhind lecturer in archæology, University of Edinburgh, 1893-1911 Sir Herbert was chairman of the Royal Commission on Tuberculosis, 1897-98, afterwards representative of H M. Government at the Berlin Congress on the Prevention of Tuberculosis. Many papers in the issues of the Scottish Natural History Society on the habits of animals and birds proceed from his facile pen. Fisherman and botanist, he has published "Salmon and Sea-trout" (1899), "Fishing at Home and Abroad" (1914), "Trees, a Woodland Notebook" (1914), "Flowers, a Garden Notebook" (1923). His "Memories of the Months" (1897) has gone through many editions. In August last Sir Herbert was appointed by the Crown chairman of the board of trustees of the newly constituted National Library of Scotland, arising from the transfer of the great library of the Faculty of Advocates as a nucleus.

Prof. Lecomte, an Officer of the Legion of Honour, is one of the two professors of botany in the Natural History Museum, Paris He was elected a foreign member of the Linnean Society in 1916, the following year becoming a member of the Paris Academy of Sciences Professor at the Lycée St Louis, 1884-1903, he joined the museum staff in 1906. Founder and first editor of the *Revue des cultures coloniales* (1897), Prof. Lecomte is author of various important works, notably, "Les Textiles végétaux et leur examen micro-chimique" (1892), and "Le Coton en Égypte" (1904).

Sir Frank Dyson, born at Ashby, was educated at Bradford Grammar School, proceeding thence to Trinity College, Cambridge, graduating second wrangler. He was also Smith's prizeman. Chief Assistant at the Royal Observatory, Greenwich, 1894-1905; he was next appointed Astronomer-Royal, Scotland, returning to Greenwich in 1910 to take up the post of Astronomer-Royal. Sir Frank was awarded a Royal medal by the Royal Society in 1921. It was recorded that among many important contributions to astronomy he had devoted special attention to investigations of the movements and distances of the stars, and of the bearing of these upon the structure of the stellar universe. He had been conspicuously successful in obtaining records of the spectrum of the corona and chromosphere during eclipses of the sun. Sir Frank is a corresponding member of the Academy of Sciences, Paris, and a foreign member of the Reale Accademia Nazionale dei Lincei, Rome.

Societies and Academies.

London.

Royal Meteorological Society, November 16—I D. **Margary**: The Marsham phenological record in Norfolk, 1736–1925, and some others. A remarkable phenological record kept by five generations of one family at Hevingham near Norwich is presented. The observations include the dates of leafing of 13 common trees, flowering of snowdrop, hawthorn, etc., and the movements of 8 migrant and other birds. The mean date for a group of seven of the plant events covering the period January-May has been worked out for each year. The annual variations are closely related to temperature and show a very definite periodicity, averaging twelve years between unusually backward springs or early springs. Recent extreme years are: early, 1912, 1921; late, 1908, 1917. The intervals have recently been shorter than the average. Comparing the plant dates in the eighteenth and twentieth centuries (taking averages for the thirty-five year periods 1751–85 and 1891–1925) of the 16 plants, 10 were earlier in the recent period, 3 were unchanged, and 3 later, possibly an indication of an earlier tendency in recent springs. Migrant birds seem independent of these conditions. The swallow's date of arrival is definitely getting later (the average for the thirty-five years 1891–1925 being eight days later than for 1751–85), in contrast to that of the cuckoo, which has on the average kept a constant date throughout the period.—C. D **Stewart**: Experiments in the shielding of rain gauges The chief difficulty met with in the measurement of rainfall is the effect of wind in decreasing the catch of a gauge owing to the eddies set up by its projecting parts At Valencia Observatory it has been found that protection is afforded in varying degrees by buildings, the Nipher shield and pits.—Harold **Jeffreys**: On the dynamics of geostrophic winds All problems of the motions of the atmosphere produced by temperature changes of large horizontal extent can be reduced to closely related problems of tides in an ocean of uniform depth, and, in the absence of friction, they can in general be solved by known methods. The theory is applied to the annual variation of pressure in Central Asia, and gives fair quantitative agreement. When applied to the general circulation, however, it gives easterly winds everywhere. Friction would considerably alter this result, indeed a steady circulation is impossible when friction is present. The only dynamically admissible types of motion with friction involve westerly circulations around the poles and systems of cyclones the height of which is comparable with that of the tropopause.

Geological Society, December 2.—R. D. **Oldham**: The depth of origin of earthquakes. Methods of determining the depth of origin of an earthquake, dependent on observations of the time of occurrence, demand records of a degree of precision, and in numbers, which are seldom available. The same objection applies to the Dutton method, based on variation in the intensity of shock; but the method is capable of a simplification which will make it applicable to any case where the area affected by the sensible shock, and the maximum degree of violence attained, can be determined. The Dutton method is sound in principle, but two important errors have been introduced in the application Acceleration has been taken as the measure of intensity, whereas the formula demands that the product of maximum acceleration and amplitude of displacement should be used, and the effect of absorption of energy in transmission has been treated as negligible. The errors so introduced are, however, opposite in sign and about equal in amount, so the depth obtained is approximately correct. The simplified method is applied to the discussion of the Italian record for the years 1897–1910, comprising 5605 distinct shocks: it is found that more than 90 per cent. of these originated at depths of less than 10 km., and mostly round about 5 km.; while only 1 per cent. originated at depths exceeding 30 km. This is in strong contrast with the depths of origin of the distant records, which seem to vary from 50 km., in a few cases, to, in most cases, 100 km. or more. From this it is concluded that where distant records accompany a destructive earthquake, the disturbance has a two-fold origin, the episeism, or surface-shock, by which the damage is directly caused, being a secondary result of the bathyseism, which is the origin of the distant record. The great number of local shocks are purely episeisms, without any recognisable bathyseism.

Linnean Society, December 17.—H. Graham **Cannon**: On the feeding mechanism of a freshwater ostracod, *Pionocypris vidua* (O. F. Müll.). The shell-cavity is incompletely divided into an anterior and a posterior chamber by the large "oral mass" suspended from the more dorsal parts of the valves. The mouth-entrance is on a level with the ventral edges of the shell. A stream of water is caused to pass antero-posteriorly through the shell by three vibratory plates. The organism is essentially a crawling form, and feeds on anything that it kicks up in its wanderings. The disturbed particles are sucked in by the water stream and eventually are transferred to the œsophagus by a pair of "food rakes" that occur in the posterior wall of the oral cavity.—R. R. **Gates**: The vegetation of the Amazon basin. The whole of the Lower and Middle Amazon basin, from the Atlantic to the Andes, lies within a few degrees of the Equator and represents the greatest area of forest in the world. Practically the whole region is clothed with luxuriant tropical rain-forest. The Amazon surpasses any other river in its drainage-area and in the volume of water discharged, the main channel being 40 to 60 fathoms deep up to Manaos (1000 miles). At high river, in June, the water-level is in many places more than 50 feet above its level at the end of the "dry" season. As the river rises, thousands of square miles of forest-country are inundated. This is known as *igapo*, and the annual flooding has striking effects on the vegetation. Among floating plants, several species of Eichhornia are common; and *Victoria regia* spreads its leaves in sheltered lagoons. Another characteristic plant along the river is a gigantic "pampas" grass (*Gynerium sagittatum*), called *flexa* in Portuguese, because the upper part of the stalk is used to make arrows for shooting turtles. Small fine-leaved bamboos of many species occur in some places. The two most numerous families in the forest are the Cæsalpinioideæ and the palms.

CAMBRIDGE.

Philosophical Society, December 7.—R. W. **Ditchburn**: The quenching of resonance radiation and the breadths of spectral lines. The virtual radiation theory put forward by Slater and others is incompatible with one or other of the sets of experimental results by Stuart, Fuchtbauer, Joos, and Dinkelacker.—G. H. **Briggs**: A photographic method of determining the mobility of recoil atoms. The method is a modification of Zeleny's, using parallel plates. The source of recoil atoms was a narrow line of mesothorium bromide on platinum on the lower plate perpendicular to the direction of the air stream. Such a source gives thorium X, thorium A, and thorium B by recoil. These atoms are carried across by the electric field to the top plate and give two bands of activity, one when there is no air current and a displaced band when there is a steady flow of air between the plates. The distribution of activity on the top plate was found by exposing it directly to a photographic plate and measuring the bands obtained with a microphotometer. No detectable difference in the mobilities of thorium X, A, and B was found, but there appeared to be a continuous distribution of mobilities from 1·24 to 1·84 with a maximum at 1·56 cm. per sec.—R. L. **Alston**: (1) Some developments in the X-ray analysis of single crystals. Müller's method of single-crystal analysis has been extended to iron crystals, for which [110] axes only are conveniently determined. For a given angle of reflexion, the axes determined by this method at a given point on the surface must lie within a limited region, if neither the incident nor the reflected beam is to be obstructed by the body of the crystal. For a plane surface the limits of this region have been calculated and plotted in diagrams for several reflexion angles. A method of analysis making use of reflexions from the continuous spectrum has also been developed. (2) The distortion of large aluminium crystals at crystal boundaries. In a test-piece composed of several large aluminium crystals, the distortion under a tensile load is less near the crystal boundaries than in the body of the crystal. X-ray analyses show that the distortion becomes progressively less as the boundary is approached, from a distance of two or three mm., but is of the same character as that in the body of the crystal, *i.e.* a shear on the same plane and in the same direction. The boundaries are more rigid than the crystals and one crystal does not slide over another.—P. A. M. **Dirac**: The adiabatic hypothesis for magnetic fields. A dynamical system undergoing an adiabatic change does not necessarily satisfy Hamilton's equations when it involves forces depending on the velocities. For a system in an adiabatically varying magnetic field, the electric forces which necessarily accompany the varying magnetic field just compensate for the preceding effect; thus the usual proof of the adiabatic invariance of the quantum integrals, based on the assumption of Hamilton's equations, is valid.—E. L. **Ince**: (1) Periodic solutions of a linear differential equation of the second order with periodic coefficients. (2) The second solution of the Mathieu equation.—G. **Timms**: The equianharmonic and harmonic envelopes of a quadrinodal cubic surface.—M. J. M. **Hill**: On the substitution of Wallis's postulate of similarity for Euclid's postulate of parallels. Addendum.—C. G. F. **James**: On a family of constructs in higher space.

EDINBURGH.

Royal Society, December 7.—W. J. M. **Menzies**: Salmon (*Salmo salar*) of the River Moisie (E. Canada). These salmon are very similar in their habits of life to salmon in Great Britain, and their scales are a good indication of their age and history. The average age of the smolts at migration is rather higher than the average age of the salmon in the northern rivers of Scotland, though they are not quite so old as the smolts in many of the Norwegian rivers. The percentage of fish which have spawned on one or more occasions is also higher than in Britain, and one salmon was found which had spawned no less than four times. The majority of fish belong to the large spring or three winters in sea class and their average weight is therefore considerable.—Fred J. **Symon**: The diffusion of salt vapours in a bunsen flame. It has been previously shown by Prof H. A. Wilson that for a bead of salt evaporating in a bunsen flame the coefficient of diffusion of the metallic vapour in the flame may be determined if the positions of two points are known where the concentration of the vapour is the same. Points of equal concentration can be found by an electrical method and the values obtained for the coefficient agree with the values previously got by H. A Wilson.—**William Cooper**: Note on copper tinted flame caps: an investigation into the colorations obtained in examining different inflammable gas mixtures, using a copper loop in the testing flame, and carbon tetrachloride in the fuel.—F A. E. **Crew**: Prenatal death in the pig and its effect upon the sex-ratio. The secondary sex-ratio in the pig is equality; the primary, as revealed by an examination of fœtuses, is not less than 150 male: 100 female. The very considerable prenatal mortality bears more severely upon the male throughout the pregnancy—E. L. **Ince**. Researches into the characteristic numbers of the Mathieu equation. This paper is a first step towards the efficient tabulation of the Mathieu functions The author gives a method by which the characteristic numbers may be evaluated for reasonable values of the parameter q. A table of the five lowest characteristic numbers is given from $q=0$ to $q=1$—T. M. **MacRobert**: The addition theorem for the Legendre function of the second kind. The addition theorem for the function $Q_n(x)$, which was established by K. Neumann for positive integral values of the degree n, is proved to be still valid when n is not an integer.—Sir Thomas **Muir**: The theory of continuants from 1900 to 1920.

PARIS.

Academy of Sciences, November 30.—L. **Lecornu**: The problem of refraction.—L. E. **Dickson**: New algebra of division.—H. Kamerlingh **Onnes**, Jean **Becquerel**, and W. J. de **Haas**: The magnetic rotatory power of some paramagnetic minerals at very low temperatures. The magnetic rotatory power of tysonite has been measured at temperatures ranging down to the boiling-point of liquid helium. From the figures obtained it would appear that the susceptibility of tysonite follows Curie's law, with a small correction Parisite and bastnæsite have also a considerable magnetic rotatory power, although less than that of tysonite. The variations with temperature follow an analogous law—C. **Sauvageau**: The localisation of bromine in an alga (*Antithamnionella sarniensis*). The author has recently demonstrated the presence of free iodine in two algæ, especially in certain organs to which the name of *ioduques* has been given. Similar cells have now been found in *A. sarniensis*, for which the name of *bromuque* is suggested, since they appear to contain bromine instead of iodine As the reagent for bromine, a solution of fluorescene is used; this is converted into eosin by the substance present in the cells. The bromine must either be free, or present in a very loose combination—E. F. **Collingwood**: A theorem of Lindelof.—J. **Sudria**: The determination of the projected displacement of a point of a body at the centre filament.—Const. **Parvulesco**: The conditions of equilibrium of a stellar cloud isolated and deprived of rotation.—G. van **Lerberghe**: The specific affinity as a function of the fugacities.—Marcel **Peschard**: Some relations between artificial ferro-nickels and a nickel iron of meteoric origin. A study of the Chinautla meteorite (1902) The measurements showed that the meteorite was in physico-chemical equilibrium whilst the artificial ferro-nickel was in a metastable state—Mme. S. **Lattès** and Georges **Fournier**. The absorption of the β-rays by matter. It has been shown that for he primary β-rays from radium E, the coefficient of absorption is a linear function of the atomic number. It is now shown that the absorption of the secondary β-rays produced by the primary γ-rays of radium rigorously follows the same law—Jean **Thibaud**: The structure of the nucleus of the radioactive atoms and the emission of spectra of the γ-rays.—C. **Matignon** and Mlle. G. **Marchal**. The thermochemistry of glucinum—Louis Jacques **Simon**: Viscosity and chemical analogy with respect to the viscosity of the metallic acetates in aqueous solution.—Paul **Hænni**: Boron in aluminium and aluminium alloys A study of the changes in the mechanical properties of aluminium and some aluminium alloys produced by the addition of varying proportions of boron—Raymond **Charonnat**. The complex combinations of the ruthenium chlorides.—R **Mellet** and M A **Bischoff**: The application of the phenomena of dyeing to the revivification of printed or written matter removed by chemical treatment In the case of an altered cheque, in which the original writing had been removed by chemical reagents, immersion in solutions of fluorescent substances (such as eosin), and subsequent examination by filtered ultra-violet light, brought out the original writing.—R **Gaubert**: The identity of fibrous limonite with göthite. The facts described prove that fibrous limonites are merely impure göthite.—P. **Russo**. Tectonic and palæontological notes on the region of Bab Moroudj.—Émile **Belot**: The dynamical and isostatic causes of the dissymmetries of the hemispheres of the earth and moon—P. **Lejay**: Storm perturbations of the electric field and their propagation to great distances.—G. **Delépine**: The Goniatite zones of the upper Dinantian and of the Chokier layer in Belgium.—Louis **Emberger** The reversion of the plasts in plants The most important phenomenon in the reversion of the plasts is the subdivision of the substratum, comparable with a sort of pulverisation of the mitochondrial substance, after the resorption of the products of elaboration (starch, pigments). The plasts, after reversion, keep their biological individuality even when they are entirely in the state of mitochondria.—Jacques **Pellegrin**: The reptiles and batrachians of the Grand and Middle Atlas.—L. **Mercier** and J **Villeneuve**: Contribution to the study of the anatomy of the head of the Diptera (*Calliphora erythrocephala*). The ptilin and ptilino-pharyngeal muscle.—J. **Glaja** and X. **Chahovitch**: The maximum metabolism and the suprarenal capsules. From experiments involving partial and total ablation of the suprarenal capsules of the rat, it would appear that these capsules play an important part, perhaps even the essential part, in the accommodation of thermo-genesis—Max and Michel **Polonovski**. A series of alkaloid derivatives with attenuated toxic power. In an earlier communication it has been shown that geneserine from the Calabar bean, in which the basic tertiary nitrogen of eserine is blocked by oxygen, while possessing the physiological and therapeutic properties of eserine, is only slightly poisonous An attempt has now been made to see if blocking the nitrogen atom with oxygen produces the same effect in other alkaloids, these compounds being named by analogy genatropine, genostrychnine, etc. It has been found that in the case of the nitrogen-oxides of atropine, hyoscyamine, scopolamine, and strychnine, the specific physiological action of the original alkaloid is preserved but that the toxic action is greatly reduced.—C. **Gessard**, E. **Fernbach**, and G. **Ruller**: Morphological modifications of the tubercle bacillus in a culture associated with a pyocyanic bacillus (melanogen variety).—— **Cluzet** and — **Chevalier**. Unidirectional high frequency current; physiological effects. By interposing an electronic valve in the circuit of a medical high frequency installation, a unidirectional current of the same frequency is obtained. A description of the physiological effects produced by these rectified high frequency currents is given.

SYDNEY.

Linnean Society of New South Wales, October 28.—W. W. Froggatt: Notes on Australian Coccidæ with descriptions of new species. Descriptions of three species of Lecanium as new. They were found in cavities in branches or trunks of forest trees. As the inner surfaces of these cavities are hard, dry, and sapless, the larvæ apparently develop into adult females with very little moisture or apparent food.—May M. Williams: The anatomy of *Lindsaya linearis* and *L. microphylla*. The apices of the rhizome, leaf, and root of both forms are of the normal leptosporangiate type. The petiolar bundle forms a single strand containing three protoxylem groups, two of which are endarch in position; the third (median) group in *Lindsaya linearis* is exarch, but in *Lindsaya microphylla* occupies various positions at different levels of the petiole, these positions varying from exarch to endarch.—A. M. Lea: Descriptions of new species of Australian Coleoptera. Pt. xviii.—W. F. Blakely: Contributions to our knowledge of the flora of New South Wales. Four new species, one each of the genera Grevillea, Tetratheca, Astrotricha, and Olearia.—R. J. Tillyard: Two new species of silky lacewings (Fam. Psychopsidæ, Order Neuroptera Planipennia) from Australia. These bring the total of species described from Australia to twelve. One is from central Queensland and is nearest to *Psychopsis gracilis*, the other is from Roebourne, W.A.—P. D. F. Murray: A note on an unusual type of secreting epithelium in the Wolffian duct of the dog-fish (*Scylliorhinus canicula*). The epithelium is one or two cells thick, the cells being of low columnar form, and was noticed both in the vas deferens and in the vesiculum seminalis.

Diary of Societies.

SATURDAY, JANUARY 2.

Royal Institution of Great Britain, at 3.—Sir William Bragg: Old Trades and New Knowledge: (3) The Trade of the Weaver.

MONDAY, JANUARY 4.

Royal Geographical Society (at Æolian Hall), at 3.30.—Mrs. Julia Henshaw: The Mountain Peaks of Canada (Christmas Lecture to Young People).

Child-Study Society (at University College), at 5.—W. S. Rowntree: The Childhood of the Race.

Royal Institute of British Architects, at 8.—Sir C. Nicholson and Sir Francis Fox: Lincoln Cathedral.

Aristotelian Society (at University of London Club), at 8.—C. A. Richardson: Paper.

TUESDAY, JANUARY 5.

Royal Institution of Great Britain, at 3.—Sir William Bragg: Old Trades and New Knowledge: (4) The Trade of the Dyer.

Optical Society and Physical Society of London (at Imperial College of Science and Technology), Afternoon and Evening.—Exhibition of Electrical, Optical, and other Physical Apparatus.

Institution of Automobile Engineers (at Royal Society of Arts), at 7.

Institution of Electrical Engineers (North-Western Centre) (at Engineers' Club, 17 Albert Square, Manchester), at 7.

Institute of Metals (Birmingham Section) (at Chamber of Commerce, Birmingham), at 7.—O. F. Hudson: The Influence of Work and Annealing on Brass.

Royal Photographic Society of Great Britain, at 7.—F. C. Tilney: Form and Content in Pictorial Art.

Hull Chemical and Engineering Society (at Grey Street, Hull), at 7.45.—A. Grounds: Fuel Economy in Steam Plants.

Röntgen Society (at British Institute of Radiology), at 8.15.—Dr. G. W. C. Kaye: (a) A Combined X-ray Tube and Vacuum Pump Unit; (b) The Industrial Uses of X-rays.—The Present Position.—A. F. Dufton: The Measurement of Radium during Radioactive Growth.

Science Masters' Association (Annual Meeting) (at Household and Social Science Department, King's College for Women), at 8.15.—The Bishop of Birmingham: Presidential Address.

WEDNESDAY, JANUARY 6.

Science Masters' Association (Annual Meeting) (at Household and Social Science Department, King's College for Women), at 10.45 A.M.—Dr. T. Slater Price: The Sensitivity of the Photographic Plate (Lecture).—Prof. Leonard Hill: Sunshine, Open Air and Health (Lecture).—At 12.—W. D. Eggar, C. H. Latter, and others: Discussion on Science and Citizenship.—A. M. Weaver, H. H. Duckworth, and others: Discussion on Laboratory Assistants and Laboratory Management. School Exhibitions.—At 5.15 and 6.—Prof. B. J. Collingwood: Demonstration of the Use of Specially Designed Electronic Models for the Representation of Chemical Actions and Electrolytic Phenomena.—At 8.15.—(Lecture-demonstration.) Arranged by Dr. C. S. Myers and F. M. Earle: Methods of Experimental Psychology.—(Demonstrations of Vocation Tests.) Miss W. Spielman: Vocational Selection.—Vocational Guidance:—Miss Stott: Intelligence Tests; Miss Roberts: Manual Ability Tests; A. Macrae: Mechanical Tests; F. M. Earle and Miss Blackett: Special Tests, Job Analyses and Rating Scales.

Optical Society and Physical Society of London (at Imperial College of Science and Technology), Afternoon and Evening.—Exhibition of Electrical, Optical, and other Physical Apparatus.

Royal Society of Arts, at 3.—Prof. H. E. Armstrong: Alice in Wonderland, at the Breakfast Table (Mann Juvenile Lectures) (1).

Geological Society of London, at 5.30.—W. N. Edwards: Fossil Plants from the Nubian Sandstone of Eastern Darfur.—V. G. Glenday and Dr. J. Parkinson: The Geology of the Suk Hills (Kenya Colony).

Institution of Electrical Engineers (Wireless Section), at 6.—Lt.-Col. K. E. Edgeworth: Frequency Variations in Thermionic Generators.

Institution of Heating and Ventilating Engineers (at Caxton Hall, Westminster), at 7.—J. R. Preston: Pump Circulation.

THURSDAY, JANUARY 7.

Geographical Association (Annual Meetings) (at London School of Economics), at 9.30 A.M.—Opening of Publishers' Exhibition and Short Address.—At 11.15.—The Hon. W. G. A. Ormsby Gore: The Economic Geography of the British Empire (Presidential Address).—At 5.—Prof. J. L. Myres: Wayside Geography (Lecture).—At 8.—Private Meeting of University Teachers of Geography. Mrs. Ormsby and others: Discussion on The Compatibility of the Training of the Geographer with the Acquisition of a University Degree in Geography.

Science Masters' Association (Annual Meeting) (at Household and Social Science Department, King's College for Women), at 11 A.M.—D. J. Berridge, E. Nightingale, E. G. Laws, and others: General Discussion: School Science Examinations.

Royal Institution of Great Britain, at 3.—Old Trades and New Knowledge: (5) The Trade of the Potter.

Optical Society and Physical Society of London (at Imperial College of Science and Technology).—Afternoon and Evening.—Exhibition of Electrical, Optical, and other Physical Apparatus.

Institution of Electrical Engineers, at 6.—Capt. P. P. Eckersley: Past, Present, and Future Developments in Wireless Telephony.

Society of Chemical Industry (Manchester Section) (at 16 St. Mary's Parsonage), at 7.—Short Papers.

Society of Chemical Industry (Bristol Section) (at Bristol University), at 7.30.—S. Robson: The Contact Process for Sulphuric Acid.

Institute of Metals (London Section) (at 85 The Minories), at 7.30.—H. J. Gough and D. Hanson: The Fatigue of Metals: a General Survey and an Account of some Recent Work. Pt. I.

Institution of Sanitary Engineers (at Caxton Hall), at 7.30.—Presidential Address.

Institution of Structural Engineers, at 7.30.—J. T. Jacques: The Manufacture and Strength of Brickwork.

FRIDAY, JANUARY 8.

Geographical Association (Annual Meetings) (at London School of Economics), at 9.30 A.M.—Exhibition.—At 10 A.M.—A. G. Ogilvie: South America and Africa as Fields for Geographical Research (Lecture).—At 11.15.—Sir John Russell: Cotton and the Nile (Lecture).—At 2.15.—Sir Halford Mackinder: The Teaching of Geography (Lecture).—At 3.30.—Dr. Vaughan Cornish: The Rhythmic Flow of a River (Lecture).

Royal Geographical Society (at Æolian Hall), at 3.30.—A. F. R. Wollaston: A Naturalist's Journey to Ruwenzori (Christmas Lecture to Young People).

Royal Astronomical Society, at 5.—*Paper received*:—J. G. Hagen: W. Herschel, Discoverer of Dark Cosmic Clouds.

Malacological Society of London (at Linnean Society), at 6.

Institution of Mechanical Engineers, at 6.—Third Report of the Marine Oil-Engine Trials Committee.

Royal Photographic Society of Great Britain, at 7.—Mrs. J. Henshaw: Camping in the Canadian Rockies (Lecture).

Junior Institution of Engineers, at 7.30.—A. J. Simpson: Notes on Salesmanship.

North-East Coast Institution of Engineers and Shipbuilders (at Newcastle-upon-Tyne), at 7.30.—W. Pollock: Star Contra Propeller.

Geologists' Association (at University College), at 7.30.

Royal Technical College, Glasgow, Civil Engineering Society, at 7.30.—G. Fairbairn: Some Applications of Cementation to Engineering Works.—J. W. Mearns: Experiences in British Guiana.

Society of Chemical Industry (Chemical Engineering Group) (at Chemical Society), at 8.—A. E. Knowles: The Manufacture of Hydrogen suitable for the Hydrogenation of Oils.—Dr. A. C. Thaysen: The Production of Hydrogen by Micro-organisms.

Royal Society of Medicine (Ophthalmology and Laryngology Sections), at 8.30.—Discussion on Inflammation of the Nasal Sinuses in its Relation to Optic Neuritis.

SATURDAY, JANUARY 9.

Geographical Association (Annual Meetings) (at London School of Economics), at 9.30 A.M.—Exhibition.—At 10.—Prof. P. M. Roxby: The Concept of Natural Regions in the Teaching of Geography, with Special Illustrations from China.—At 11.15.—Discussions held concurrently in separate rooms:—C. G. Beasley and others: The Place of Geology in a Two Period a Week Geography Course.—C. D. Forde and others: Detail in Geography Lessons.—Major A. G. Church and others: Geography in Relation to other School Subjects.—Miss R. M. Fleming and others: Geography for the Younger Children in Primary Schools.

Royal Institution of Great Britain, at 3.—Sir William Bragg: Old Trades and New Knowledge: (6) The Trade of the Miner.

SATURDAY, JANUARY 9, 1926.

Statistics in Administration.

A LARGE amount of work has been done in developing statistical methods on the scientific side, and it is natural for any one interested in science to hope that all this work may be utilised in commerce and industry. There are signs that such a movement has started, and it would be unfortunate indeed if those responsible in practical affairs fail to take advantage of the improved statistical machinery now available.

There are, admittedly, many difficulties in the way of introducing into any business a new type of investigation, and, even when these are overcome, we are aware that much of the statistical work of business is, and must be, mere tabulation—a dull form of accountancy that ends before the interesting process of analysis, investigation, and interpretation begins. In some of this tabulation, the form in which results have to appear is dictated by Act of Parliament, so we are deprived of using any ingenuity in arranging the figures. This is always regrettable to any one really caring about the subject, for though tabulation at its worst is about as dull as anything can be, it is made by skilful hands the first and by no means the least important element in any complete statistical investigation. Here we reach the beginning of things: the statistician may have specific problems to solve and may be able to start the preliminary work as he likes; he can then feel most happy about his results, and he has the best chance of making those incidental discoveries which are interesting in all scientific work and often very valuable in statistical work in business. But he does not often have such a chance: over and over again some sort of statistical tabulation has been going on, and expense or delay puts rearrangement outside the realm of practical politics. The problem is then: " What is the best we can make of figures in the particular form ? "

Here, and in other cases, the trained man has the best chance of drawing useful conclusions, but it would be wrong to expect any statistician unfamiliar with a particular business to find out as much from statistics as would be possible if he knew a business well: ignorance of a business may lead to mistakes which experience instinctively avoids. Here possibly we see the fear, so far as it exists, of the professional statistician: and in a sense some fear, or at any rate some hesitancy, is right; but the answer is not that the trained man should be avoided because he may make a mistake when called in to examine statistics of a business with which he is unfamiliar, but that in any business where statistical work is essential, a trained man should be on the staff. In some businesses trained men are employed as a matter of course: no respectable life assurance company would, for example, dream of conducting its business without having an actuary to examine and advise.

One part of statistical work often wanted in business is called by the fairly descriptive name of "cost accounting." In its simplest form it is merely the setting out of the cost of production of an article, but in many cases the problem is of much complexity, and in some ways it involves methods and principles like those adopted by an actuary in ascertaining the periodic payment necessary to meet a more or less complicated benefit. It seems, from this point of view, a little strange that this work should have fallen to the accountant rather than to the actuary, but both professions are trained to some extent in statistical work, and accountants, being auditors or on the staff for other purposes, are more readily available and have, at any rate, a superficial knowledge of the particular business.

It happens occasionally in practical work that a new process or a change in procedure or manufacture is suggested, and it is thought worth while to make a trial of the process. Any single trial may be a failure and yet the process may be an improvement on the old: the proportion of failures may be less. A success may depend on the combination of a number of causes. A trial may, however, be an expensive matter. The trained statistician who has studied those awkward problems of small samples will alone be able to read the answer correctly and to judge properly from a few experiments whether the proposed reform is worthy of adoption. Much of the statistical work done in biology at Rothamsted under Mr. R. A. Fisher is necessarily based on small samples, and the original work by "Student" in *Biometrika* seems to indicate a field of work on small samples in a practical business.

Generally speaking, however, the statistical work we have in mind would be of wider scope. It is only possible to judge of the success of each part of a business by investigation, and in many instances a study of a simple kind can tell a good deal, but if there is interlocking, if incidental profits are thrown up or if an apparent loss can be afforded in one part of the business because it is always associated with a large profit elsewhere, then the work may assume a troublesome complexity. We should anticipate that a well-trained practical statistician with a "roving commission" over all the figures produced in a business would save his salary over and over again.

We may now consider what training is available for the more highly skilled statistical work. Probably the most advanced school is that of University College, London, where Prof. Karl Pearson and his assistants and pupils have done so much original research both theoretical and practical. Then there are some other colleges of the University of London teaching the subject, sometimes, however, from a rather special point of view, *e.g.* at the London School of Economics. There are also opportunities for study at Cambridge and elsewhere, and there is a comparatively newly constituted school under Prof. E. T. Whittaker at the University of Edinburgh. In the United States the subject is taught fairly generally in some form or another, but, judging from the books published, it is sometimes only dealt with superficially. Apart from the universities, probably the best places to learn the subject—and for certain businesses the schools, if they can be so called, are probably as good as any—are the Institute of Actuaries and the Institute of Chartered Accountants. To a certain extent, this remark also applies, of course, to the other accounting bodies and the Faculty of Actuaries, but to a lesser extent because the membership and the influence of these bodies are less. Many accountants would probably have difficulty in following much of the modern research work in statistics, owing to its mathematical nature, but, if we may judge by their examinations and transactions, actuaries should have no real difficulty in this respect.

Possibly the simplest way of improving statistical work in a business where little has yet been done is to appoint to the staff some one who has studied statistics theoretically, and can be encouraged to learn as much as possible of the business. Afterwards some of the younger members of the staff who do not, when appointed, possess the necessary qualifications, might be encouraged to acquire them, much as insurance offices and banks encourage members of their staffs to study theoretically the subjects with which they deal practically in their daily work.

Some Problems of the Oil Age.

American Petroleum: Supply and Demand. A Report to the Board of Directors of the American Petroleum Institute by a Committee of Eleven Members of the Board. Pp. xiv + 269. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1925.) 15*s*. net.

IT is generally recognised to-day that there are few commodities the failure of which to appear in the world's markets would cause more inconvenience than that of petroleum oil, which either as a fuel or as a lubricant is a vital necessity to many services of transport and production, apart from its still considerable use in many countries for lighting and heating.

The oil age, which began five and twenty years ago with the coming of the internal combustion engine, will probably endure for a considerable period, until

Nature and man in co-operation develop other means of power production. Nevertheless, authorities agree that the exhaustion of oil is proceeding far more rapidly than any known possibility of replacement. Men of science are only at the beginning of their investigations as to whether Nature is replenishing her stores of oil or not. It is true that there is a deep-rooted belief amongst practical oil men, based on empiricism rather than upon science, that lower down in the earth large supplies may lie, as yet only dreamt of in oil philosophy. Some support of this view is derived from the fact that the early primitive oil-wells were all shallow, and that even in 1861 Col. Drake in Pennsylvania struck oil at 69 feet.

At the present time, much oil comes from wells of 2000 to 3000 feet, and occasionally deeper. Oil technologists are not unnaturally beginning to talk of putting the drill down to oil sands at 5000 feet, whenever and wherever the prospect of a sufficient and remunerative supply may justify such a course. Oil will also be worked in due season to a far greater extent than at present from shales and other oil-bearing materials, which exist in large quantities in many other countries besides America. This latter source of supply may conceivably meet the oil needs of the world long after natural oil is wholly or nearly exhausted. It is not practicable, however, to say definitely long beforehand when a particular deposit will be ripe for commercial exploitation, since this depends on the richness of the material in oil and by-products as well as upon cost of working and the degree of competition of natural petroleum.

In Great Britain the consumption of oil products, including supplies to ships' bunkers, exceeds five and a half million tons per annum, nearly all imported. The United States uses about twenty times as much oil as we do with a population three times as great as ours. But America is at one and the same time a producing, importing, refining, consuming, and exporting country in the matter of oil. Many countries depend in whole or part upon the U.S.A. for supplies of lighting and lubricating oils and motor spirit. A possible extension of imports of oil into U.S.A. may occur, but will she maintain or restrict her exports? British supplies of oil products are drawn principally from Persia, America, the Dutch East Indies, and Mexico, with some production from Scottish shale and a modest amount of benzol from coal.

There is no need further to labour the point that the most advantageous use of Nature's stores of oil, coal, and water-power is and must always be of widespread interest. We may welcome, therefore, the thought-stimulating report recently published by the American Petroleum Institute on the prospects of oil supply and demand over the next fifty years in the United States. Though the report is limited geographically, the estimation which it contains of general factors likely to affect oil production and consumption is of wider than purely American interest. The report is in the main a business document on an economic basis and is only incidentally scientific and technical. It is no disparagement of so complex a survey to say that reality is likely to differ from estimate in many cases, seeing that numerous disturbing though occasionally counter-balancing factors must arise. Even general tendencies may be deflected and greatly modified. Nevertheless, the report is valuable from its wide outlook notwithstanding the geographical limitation which has been imposed.

A previous American oil estimate, known as the "White-Steburger," dealt, some six years ago, with the potential oil reserves of the whole world, but on a geological rather than an economic basis. That survey created some uneasiness from the suggestion that American fields were rapidly nearing exhaustion and that supplies in other countries, of natural petroleum at any rate, would probably meet requirements only for some sixty years or so. Men of practical experience in the oil trade in America and elsewhere were able to allay anxiety to a considerable extent by pointing out, on the basis of past experience, that the oil industry usually does much better in actual output than might be prognosticated by prudent men of science working upon uncertain data and necessarily incomplete investigation. The increase since then of production in California and Texas and in fields outside of the United States has confirmed the impression that the "White-Steburger" estimate was an extremely conservative one.

The 1925 report bears the signatures of eleven men of recognised standing in the American oil industry. No attempt is made therein to frame an estimate of the potential quantity of oil in lands in the U.S.A. "not yet proved," which are classified as "areas within which oil-fields may be found," of a total area exceeding eleven hundred million acres. The "present producing area" is about two million acres and "proved undeveloped areas" amount to another million acres approximately. The number of American wells now producing is about 300,000, yielding an average of one ton a day each. The world's production of crude oil in the last sixty years has practically doubled itself every ten years or so, until it has reached an annual total of about 136,000,000 tons, of which the American proportion is about 70 per cent.

The oil trade, however, has now reached a point at which a steady rather than a sensational progression may be expected. It is stated in the estimates in the report that existing proved fields may yield by normal flowing and pumping some six or seven years' supply, but it is anticipated that, if prices and products should justify a more complete draining of wells by water-flooding, mining, and other intensive methods, some five times that quantity may be obtainable in addition. Oil is expected to be found also at lower depths than those of existing wells, and eventually will be largely produced from shale, coal, and lignite. The liquid possibilities of these three classes of solids run into billions of tons and might last for centuries From one source or another, with adjustments as between oil, coal, and water-power, and allowing for economies in methods of production and utilisation, America expects to meet its oil needs for many years beyond the period of fifty covered by the report.

On the side of utilisation, the expectation is that motor facilities will be still more widely used. The report visualises "a nation on wheels." The present "saturation point for automobiles" is estimated at 27,000,000, *i.e.* one family, one automobile. The power production of cars in one year is 3,600,000. The U.S.A. population and number of families in 1950 are estimated each at about 50 per cent. increase over the figures of 1920, and the number of automotive engines, including motor cycles and aeroplanes, is calculated to reach by 1950 a total of nearly forty-five millions, as compared with some fourteen or fifteen millions in 1924. "Some figures!" But wonderful things happen where oil is concerned. It must not be supposed that the demand for motor spirit will be proportionately increased. A far lower rate of consumption is expected with improved engines. Britishers will compare the American 1924 figures with their own modest total of less than one and a half million motor vehicles, and will also hope for engines that will give them an additional mileage per gallon. In addition to the early adoption of more economical automotive engines of the types that use motor spirit, an increase is also looked for in the case of Diesel engines, in which heavy residual oil is used on a more economical basis than for steam raising. British marine engineers have recognised the advantages of the Diesel engine in many types of ships, but they have faith in steam turbines for very high-powered vessels. On this side of the Atlantic improvements of the turbine are anticipated, which incidentally may economise fuel consumption whether oil or coal.

Intensive drilling and refining, and the use of geophysical apparatus and other means as an aid to oil exploration, are well known to technologists generally, who are also watching progress in various methods of extraction of oil from coal and the further development of electricity by water-power. These matters are suggestively touched upon in the American report, but in some cases very sketchily. We are not carried very far when we are told that developments "may prove the possibility" of the utilisation of finely powdered coal or coke either by itself or in suspension in fuel oil, fed to motors. The data of actual tests under working conditions are needed to indicate whether real progress has recently been made or not.

Our brief study of this subject on the whole confirms the expectation of many good authorities that the replenishment of the world's cruse of oil will be maintained for some considerable time to come.

The Inspiration of Chemistry.

Three Centuries of Chemistry: Phases in the Growth of a Science. By Prof. Irvine Masson. Pp. vi+191. (London: Ernest Benn, Ltd., 1925.) 10*s*. 6*d*. net.

IT is a common complaint that men of science do not write readable books. We hear it especially to-day among those who, despite their complete ignorance of science, are known as "well-educated" people. The complaint is levelled in particular against representatives of physics and chemistry Naturalists, it is said, have done better; even Darwin's great original contributions to science were issued in the stream of general literature and were intelligible to the non-scientific. The complaint about physicists and chemists has recently grown louder, because educated people know it is in physics and chemistry that great things are happening. It is exasperating to feel that vast horizons of new knowledge are being opened out, that something like a revolution of thought is taking place, and yet not to be able to get some clear notion of it. True, some excellent simple expositions of this new science have been written. They fail, however, because there is nothing to which they can be linked in the mind of a reader with no knowledge of the elementary principles of the old science. Unless he has something like a vista of the chief facts and the chief stages in the development of our knowledge of physics and chemistry, how hopeless it is to give him any conception of what the new knowledge really means!

We, who live in science, are apt to say that we are not answerable for this grievous popular ignorance. No doubt that is true to some extent, perhaps to a large extent. But it is not wholly true. Leaving aside the influence which our world has exercised on school-science, there remains the question whether we have not failed in another direction.

It must almost inevitably happen that the days of formal education leave a man very defective in knowledge—it may be almost blankly ignorant—of some department of human thought. Consider, for example, the young men coming to-day to study in our universities in numbers, without any training in the language, literature, and history of Greece and Rome—without even any knowledge of "roots" to unmask the pretensions of words like catalysis and karyokinesis, or to elucidate even the simplest Latin etymology. These people, if they have mental health, will in time seek to cover their intellectual part-nakedness; and they will not find it difficult. They may forgo the grind of grammar and forgo even the learning of the languages altogether, and yet obtain, in an easy-chair, some abiding comprehension of what Greece and Rome meant to humanity and some share of the gifts they have bequeathed us.

Let us suppose the commoner case of our middle-aged or elderly contemporaries, who left school and college after an education that excluded any enlightenment in physics and chemistry. What can be done with them? What are they likely to have done for themselves to repair the omission? Nothing. But let us not be too hard on them. It is not easy to pursue laboratory work in the leisure and precincts of the average home. Attempts to do this were made at another great period of chemical upheaval. Even Dr. Johnson himself discovered a "love of chymistry which never forsook him." Boswell unfortunately is very meagre in this part of his story. He observed in Johnson's library "an apparatus for chymical experiments," and records coldly that at the age of seventy-four years the Doctor "attended some experiments that were made by a physician at Salisbury on the new kinds of air." Of what Johnson himself did, the only occurrence that seems to have roused his biographer to animation and detailed record was the great man's purchase of an ounce of oil of vitriol, for a penny instead of an expected three-halfpence. There is evidence that other men of letters of the time were striving to keep in touch with chemistry. Francis Horner, a picked man of the first Edinburgh Reviewers, attempted experiments at home, but, after some misfortunes, had to conclude regretfully that it was scarcely practicable to distil sulphuric acid in a living-room.

If we have to admit that the difficulties of amateur self-education in chemistry after school and college days reduce us to the exclusion of experiments, there seems to be only one hope left. It is that we can tell the story of the science in simple yet vivid terms, with a clear design and sequence, with vast and carefully considered elimination, with accurately timed and adjusted stress, with human regard to the discoverers as men as well as intellectual regard to their own and other men's philosophies; and we must do it with the best literary skill we can command.

It is this that Prof. Masson has attempted to do in the book before us. He has succeeded so well that a reviewer's difficulty is here to moderate duly his terms of praise. Let it be said, then, at once, that the author's equipment for his task is by no means wholly of his own making. Looking into his ancestry, a Mendelian could probably explain the exact amounts and proportions of scientific and literary talent which Prof. Masson has had as a free gift. Then there are Scotland, Australia, and the great metropolis, and great teachers that all count for a good deal. With this equipment Dr. Masson has attempted "to show the very broad foundations that were provided to sustain the present structure of science, and to what manner of men and circumstances we owe the laying and the consolidation of those bases (Chaps. i.-iv.). Next, to show in action the application of this process to chemistry, and the issue of a dominant motive which has given continuity to the whole subsequent trend of the science (Chap. v.). The ensuing phase in chemistry displays the long struggle between the new mode of thought and the ancient philosophy, ending with the eighteenth century in a solution of the central problem and a final ousting of medievalism (Chaps. vi.-x.). In the next phase the key-problem has taken on a deeper meaning, and the arrival of its successful interpretation is set forth as we know it to-day, while note is taken of the oncoming of still another era (Chap. ix.)."

The result is a book which deserves and will doubtless obtain the widest currency, for it is a work both of literature and science. It will hold the attention of "those who do not understand the technicalities of chemistry and physics, but are interested either in the evolution of modern thought or in applied logic." Above all, it will be useful to those who call themselves chemists. A real danger of these days of high pressure in chemical studies is that we may grow narrow intellectually. It would be a calamity if, in the intensive cultivation of our plots of science, we were to grow heedless of the general drift of our work. It is not at all inconceivable that science might otherwise lead to the sort of distortions and extravagances that the world has suffered, in the realms of thought and education, from the illiberality of humanists and super-humanists.

The length to which this notice has already extended precludes any comment or criticism on detail. The object has been only to indicate the high importance of the task which Prof. Masson set himself and to convey the reviewer's impression that it has been achieved with very remarkable success. He would heartily congratulate Prof. Masson on having made a most valuable and scholarly addition to general literature in the name of science.

A. SMITHELLS.

The Maori of Olden Times.

New Zealand Board of Science and Art. Manual No. 4: *The Maori as he was; a Brief Account of Maori Life as it was in Pre-European Days.* By Elsdon Best. Pp. xv+280. (Wellington, N.Z.: Dominion Museum, 1924.) n.p.

MR. ELSDON BEST has written for the New Zealand Board of Missions an account of the Maori when they first became known to Europeans, interpreted in the light of later knowledge, and by his own familiar acquaintance with native customs and ideas. The work covers the whole range of Maori anthropology.

Two distinct physical types of native are said to occur. One, long-headed and prognathous, approaches the Fijian; the other, with broader head and orthognathous, is the common Polynesian. The hair is commonly black and waved, though frizzled hair is sometimes seen.

In a chapter on traditional history, Mr. Best very briefly reviews the native accounts of the peopling of New Zealand, especially those preserved by tribes on the east coast of North Island. These traditions indicate an original Polynesian migration from lands in the west called Uru and Irihia. Following Conder and Percy Smith, it is suggested that Uru is the Biblical Ur, and that Irihia is connected with Sanskrit and Dravidian words for rice—*vrihi* and *ari*. These are mere guesses. A summary is given of the more important Polynesian voyages which led to the settlement of New Zealand.

The mythology and folklore form an interesting chapter in which the author stresses the Maori genius for personification and its application to natural phenomena, and the evolution of such myths as that of the green-stone, fabulous monsters and fairies. A summary of the religious ideas of the Maori follows, a subject with which Mr. Best has dealt more fully elsewhere (cf. NATURE, June 9, 1923, p. 790).

Like other Polynesians, the Maori were communists in social custom. The proceedings of the family, clan and tribe, and the power and prestige of the chief, were closely influenced and controlled by public opinion, and the same force maintained law and order and regulated the relations of the three classes of the community, chiefs, commoners and slaves. The Maori was a sociable being, living in village communities. He took his meals in the open, and was hospitable and fond of conversation, story-telling and amusement. Men only engaged in occupations in which *tapu* was prominent, such as house-building, canoe-making, crop-planting and the obtaining of food. In the last work women helped, especially in gathering shell-fish, but they were more especially engaged in preparing and cooking food and in the manipulation of the flax fibres and the manufacture of clothing, plaited mats and baskets. This chapter concludes with a brief account of birth, marriage and funeral customs. Birth, death and exhumation were marked by much ritual; marriage and burial by less. An infant underwent the rites of *tohi* and *pure*. The first is described by Mr. Best as a kind of baptism, the second as a greeting to the child. Betrothal, sometimes of infants, might be arranged before marriage, and marriage by capture sometimes took place. The dead were buried in a sitting position, but the remains were exhumed with much ceremony after a few years, and finally conveyed to a distant cave or hollow tree.

Mr. Best's chapter on the arts of life occupies half the book, and is exceedingly well illustrated. He describes the arts of pleasure, war, agriculture, woodcraft, textiles, clothing and ornaments, habitations and fishing. The Maori's implements were crude and primitive. Fire was produced by rubbing one stick on another. There was no loom; the cloaks of flax fibre were made by interlaced and tied threads, not by true weaving. Adzes were of stone, agricultural implements of wood. A simple drill was used, and Mr. Best figures a tree-felling machine on the principle of the Roman *ballista*. House-building is described in detail. The Maori was an expert carver. His decorative art is remarkable for curvilinear forms, in contrast to the commoner rectilinear designs of Polynesia. Tattooing was practised by both sexes; by men on face and body, by women usually on the lips and chin only.

Fishing and bird-trapping provided the chief animal food of the Maori. The dog and rat were articles of luxury. Fishing nets and traps were of great variety. Some, of immense size, astonished early European visitors.

Mr. Best has produced a very useful little book, which will inform and interest the traveller or the tourist, and provide a useful syllabus for the serious student of Maori thought and custom. There is a short bibliography, a good index, and more than 130 illustrations of persons and objects.

S. H. RAY.

Fundamentalism and Science.

The Relation between Science and Theology: How to Think about It. By C. Stuart Gager. Pp. vi+87. (Chicago and London: The Open Court Publishing Co., 1925.) 1 dollar.

THIS book is a very useful piece of anti-Fundamentalist polemic. The underlying causes of that strange reaction have been diagnosed by Prof.

Kirsopp Lake, of Harvard, as "general but imperfect education and democratic government." If that be so, perhaps the United States will not be the only country to be affected by this strange recrudescence of superstition.

No doubt Fundamentalism will one day meet its Voltaire, but he will be neither man of science nor philosopher, but theologian. It is only the theologian who can appreciate the imbecility of this revival. Properly speaking, it is not a revival, for the Fundamentalist has forgotten much of the theological thought of the past, while learning little of that of the present.

Mr. Stuart Gager has attempted to disseminate a certain amount of light where it is badly needed by delivering popular lectures, and by publishing their substance in the present volume. The book is to be commended for two reasons: (1) The author has taken a good deal of trouble to understand and to explain what is really meant by literary criticism of the Bible, and (2), he has concentrated not upon the *results* of the natural sciences, but upon the *method* of science in general. Thus, he has gone the right way to work; for no one who has a clear grasp of the methods and results either of the literary and historical criticism of the Bible, or of the natural sciences, would find Fundamentalism intellectually or emotionally attractive It is really a question of whether a person is or is not capable of following an argument, or weighing evidence, or indeed used to any kind of systematic thinking Neither Mr. Gager nor an angel from heaven could do much for people whose limitations or obstinacy preclude them from availing themselves of his help

Mr. Gager's title—"The Relation between Science and Theology," not "Science and Religion"—indicates that he understands the nature of the problem; for the quarrel is not between the incommensurables, science and religion, but between science and some particular theory about our religion, its origin and its meaning. In justice to theology it has to be remembered that Fundamentalist theology, unlike that, for example, of St. Thomas Aquinas, is intellectually not respectable.

The general reader will not find this book any less valuable on account of its somewhat naive metaphysical point of view. For example, the conceptions of *cause* and *change*, though they play some part in the argument, are not subjected to any radical analysis. But Mr. Gager is not writing for students of Kant, who rarely succumb to the seductions of Fundamentalism.

Mr. Gager's work, simple, straightforward, and well informed, deserves a wide circulation; especially perhaps in some parts of the United States, where theological thought seems to be more remote from the precincts of reason than it is, at present, in Great Britain.

J. C. HARDWICK.

Our Bookshelf.

Le Cerveau et le cœur. Par Prof G. Fano. Traduit de l'italien par G. Caputo. (Nouvelle Collection scientifique.) Pp. vii+211. (Paris: Félix Alcan, 1925.) 10 francs.

THERE is often a baldness of statement necessary in contributions to scientific journals which freezes the interest of a sympathetic but non-scientific reader. This is partly because wide general conclusions cannot be appended to each single published contribution. At intervals, however, during a career of scientific work, it is possible for some to touch on the deeper aspect of things. Prof. Fano has published a series of lectures in book form which can be recommended to the biologist and to the general reader, to one for an attempt to probe the *causa causans* of his science, to the other for its exposition of scientific methods and of the trend of physiology.

In introducing the author to the French public, Prof. Gley says, "Fano n'est pas seulement un expérimentateur: c'est un penseur." The truth of this statement is made evident to the reader as he finds described and discussed various problems of research, each in turn. The properties of living matter are dealt with at some length and from many aspects. Probably more satisfying to the majority of readers are later chapters, which describe the effects of ablating at different levels the higher nerve centres of the tortoise, *Emys Europæa*, and the interpretation of the results in relation to the will and to inhibition. A parallel deduction might have been made from the similar work of Sherrington and of Magnus on higher animals.

Other chapters recapitulate the earlier work of the author on electrical responses of cardiac muscle and his observations on the heart of the chick, and give insight into his minute technique. The book is a useful collation, in a language other than Italian, of the researches and philosophical views of this Italian *doyen*, and takes a worthy place among its fellows in the "Nouvelle Collection scientifique" Alcan

Air Ministry: Meteorological Office. The Observatories' Year Book, 1922: Comprising the Results obtained from Autographic Records and Eye Observations at the Observatories at Aberdeen, Eskdalemuir, Cahirciveen (Valencia Observatory), Richmond (Kew Observatory), and Benson; in continuation of the former British Meteorological and Magnetic Year Book, Parts 3 and 4. (M.O. 259) Pp. 337 + 6 plates. (London: H.M. Stationery Office, 1925.) 63*s*. net.

THE elements dealt with in the volume are barometric pressure, air temperature, humidity, rainfall, sunshine, wind velocity and direction, cloud and general weather. Records are tabulated for each hour. Details are given of the exposure and surroundings of the different instruments, and photographs show generally the position of the instruments. The work consists mostly of tabular results closely printed. Much information is afforded for minute study on various subjects of meteorological importance. At Eskdalemuir the diurnal variation in the components of magnetic force on quiet and disturbed days is given. The variation of the several components is shown by diagram for the year and for the several seasons, and average results are given for the years 1911–1921; special attention is also given to seismology. At Valencia the outstanding features for 1922 are said to be the cold weather of April, the prolonged low temperature, practically continuous from the middle of June to the beginning of November, and the small rainfall of October and November. At each of the four observatories (omitting Benson) the highest temperature during the year occurred at the end of May, and the minimum about the middle of January; at Kew the minimum reading was repeated on April 2, the highest and lowest readings occurring within 52 days of each other. The largest hourly measurement of rain at Aberdeen, Eskdalemuir, and Kew occurs in day hours between 8 A.M. and 5 P.M.; at Valencia it occurs between 1 and 2 A.M. The smallest hourly measurements occur between 7 A.M. and 1 P.M., except at Eskdalemuir, where it occurs from 8 to 9 P.M.

The Hidden Zoo. By Leslie G. Mainland. (The Broadcast Library.) Pp. 205+8 plates. (London: Hodder and Stoughton, Ltd., 1925.) 3*s.* 6*d.* net.

MR. MAINLAND is already well known as a delightful writer of popular articles on the Zoo, and this book is no less fascinating and amusing than his earlier volumes. In this collection of articles the author takes us behind the scenes at the Zoo and tells of the worries and anxieties of keepers and staff, and of the amusing and sometimes disastrous escapades of some of the animals. Its chief merit is, perhaps, the revelation which it makes of the large amount of careful and valuable research work which has to be done and is done by the staff in their endeavours to secure the best possible results for the animals in captivity, and the care which is constantly exercised in order to obtain the most natural conditions, consistent with confinement, for their charges. The nature of the correct food, the times at which it should be given, the rearing of the young, even the breeding of suitable foster mothers for the young of birds, are all matters demanding close observation and experiment. Mr. Mainland tells how these problems have been faced and solved. The book is charmingly written in humorous vein and is eminently suitable for reading to children. Yet the professional zoologist will find in it all sorts of odd facts of natural history of real scientific interest.

Food and Health. By Prof. R. H. A. Plimmer and Violet G. Plimmer. Pp. vi+64. (London: Longmans, Green and Co., 1925.) Paper cover, 2*s.* net. Cloth, 3*s.* 6*d.* net. Food Chart, 3*d.*

THE purpose of this little book is to explain to a lay public the principles on which a complete dietary is based, directing special attention to the errors which are commonly made in the selection of foods for human consumption. The central idea is comprised in a "square meal" expressed diagrammatically; the carbohydrates and fats or the "fuel foods," together with water and salts, constitute a central circle, whilst the four corners to form the square are filled up by proteins of good biological value and foods containing one of the three vitamins respectively. A coloured diagram shows at a glance both those foods which should be included in a complete dietary and also those of similar nature which should be either excluded or, if included, should not form the staple representatives of their class. The authors consider that the average dietary contains too little vitamin B to balance the remaining constituents, especially the carbohydrates. The work is written in a pleasant style and can be read with profit not only by the public, to whom it is more immediately addressed, but also by those whose training should enable them to express an authoritative opinion on the subject.

Úvod do Chemie Radioaktivnich Látek. By Dr. A. S. Russell. Translated by Prof. Dr. A. Šimek. Pp. x+116. (Brno: A. Piša, 1925.) Kč 20.

ALTHOUGH it was Bohemia which supplied the classical pitchblende in which radium was first detected, the Czech scientific literature does not possess any volume on radio-activity. Dr. A. Simek, who is professor of physical chemistry at the Masaryk University of Brno, has, therefore, translated Dr. A. S. Russell's "Introduction to the Chemistry of Radio-active Substances" into Czech for the benefit of his students.

In his preface the translator points out that to write a treatise on a subject of this kind, the author must himself have conducted extensive original researches on the phenomena of radio-activity. This was one of the reasons for selecting Dr. Russell's text-book, which is also better adapted for translation than the more comprehensive treatises, since the latter would be in need of revision almost as soon as the translation was in the hands of the student.

The Czech edition closely follows the original work, but additions have been necessitated by the latest progress in this ever-expanding branch of physical chemistry. In his preface Dr. Šimek acknowledges the author's careful revision of the original English edition for the purpose of bringing the translation entirely up-to-date.

Strength of Materials. By Prof. Alfred P. Poorman. Pp. xi+313. (New York: McGraw-Hill Book Co., Inc., London: McGraw-Hill Publishing Co., Ltd., 1925.) 15*s* net.

THERE appears to be a large demand in the United States for good engineering text-books of a theoretical type but of rather elementary standard. According to the preface, the present work is intended ". . . for use in undergraduate courses in Mechanics . . ." and it might serve as a useful introduction to the subject in the junior classes of engineering schools in Great Britain. The ground covered is not extensive, being confined to a discussion of the more ordinary problems in the theory of beams, shafts, and columns. Combined stresses are only dealt with in a few very simple cases, and the amount of elastic theory given is decidedly meagre, even for an introductory work. A large number of practical examples to be worked by the student are distributed throughout the work, appearing at the end of almost every article. The book is, however, carefully written, and the various figures throughout the text have been admirably reproduced. The treatment of the subject matter follows orthodox lines, and two chapters in the later part of the book are devoted to special methods of solving problems on the deflexion of beams.

An Ancient Wooden Structure at Ipswich.

In the course of excavations—carried out by means of a grant from the Percy Sladen Memorial Fund—in the brickfield of Messrs. A. Bolton and Co., Ltd., in the northern portion of Ipswich, a discovery has been made of the remains of a wooden structure that may be of considerable antiquity. As is widely known, there are preserved, in places, in the sides of the small, dry valley where the brickfield is situated, two superimposed "floors," or occupation levels, in which a large number of flint implements, flakes, and hammer-stones, together with hearths, fragments of very coarse and primitive pottery (these were found at two sites only), mammalian and some human bones, have been discovered The investigation of these "floors" has been conducted, at intervals, for the last fifteen years, and, during this period a very complete knowledge has been acquired, both of the type of specimens occurring at these levels, and also of the geological happenings since the time when these prehistoric remains were deposited in the valley.

The excavations that have been carried out this year were confined to the north-east part of the brickfield, and have exposed, in the small escarpment of the valley at this spot, the following deposits: (1) surface humus to 9 inches; (2) sandy, stony hill-wash to 8 feet, passing into (3) reddish sand, with small ferruginous concretions, often tubular in form, to 2 feet; (4) traces of Upper Floor resting unevenly upon (5) grey sand, to 2 feet, with (6) Lower Floor at base, resting unevenly upon (7) yellow sand. This yellow sand, upon which the lower floor rests, is found also on the south side of the valley, and, where containing water, has in it numerous roots of trees—*Pinus sylvestris*—that flourished, evidently, on the ancient land surface represented by the lower floor. It may be assumed that the sand was dry when these trees—which do not favour wet ground—were growing, and the preservation of their roots is almost certainly due to the present water-logged condition of the sand.

In the recent excavations a quantity of these roots were met with in the sand underlying the lower floor, and it was at this latter level that the remains of the wooden structure—now to be described—were found. As will be seen from Fig. 1, this consists of two short pieces of wood, of plank-like form, which overlap where they meet, and were placed with one of their longer edges buried superficially in, and more or less vertical to, the surface of the underlying sand. The "plank" nearest the observer is 2 feet 6 inches in greatest length, three-quarters of an inch in greatest thickness, and 8 inches in greatest width; while that farthest away from the observer is 1 foot 10 inches in greatest length, 1¼ inches in greatest thickness, and about 7 inches in greatest width.

These pieces of wood, which, by their characteristic form, were evidently split off a trunk of large size, are of oak, and exhibit, on one or other of their surfaces, clearly defined marks of cutting with some kind of axe. Behind these planks, that is, on the side farthest away from the observer, were piled a quantity of flints and other good-sized stones, and a row of (?) larch stakes, not set closely together—roughly pointed, and driven to a depth of about 1 foot into the underlying sand. These stakes—one of which can be seen in the photograph (Fig. 1)—have most of their upper portions missing, and were not inserted vertically, but inclined at an angle, with the sand surface, of about 45° towards the east: the apex of the angle formed by the intersection of the ends of the two planks (Fig. 1) pointing, approximately, to the north-west. Between the planks, and the supporting mass of stones, were found traces of clay in which were partially embedded numerous branches of (?) larch, and it is supposed that these branches, together with the missing upper portions of the stakes described, extended for some distance above the planks, and afforded a shelter from the sun or wind. The heap of stones farthest away from the observer (Fig. 1) was, unfortunately, moved before the photograph was taken, but occupied, originally, a position in close contiguity to, and about opposite the middle of, the "shelter," and, as among this heap there were found hammer-stones, one large, roughly-made *racloir*, numerous flakes, and some burnt flints, associated with blackened, carbonaceous sand, it seems that there was some sort of habitation where the manufacture of flint implements was carried on.

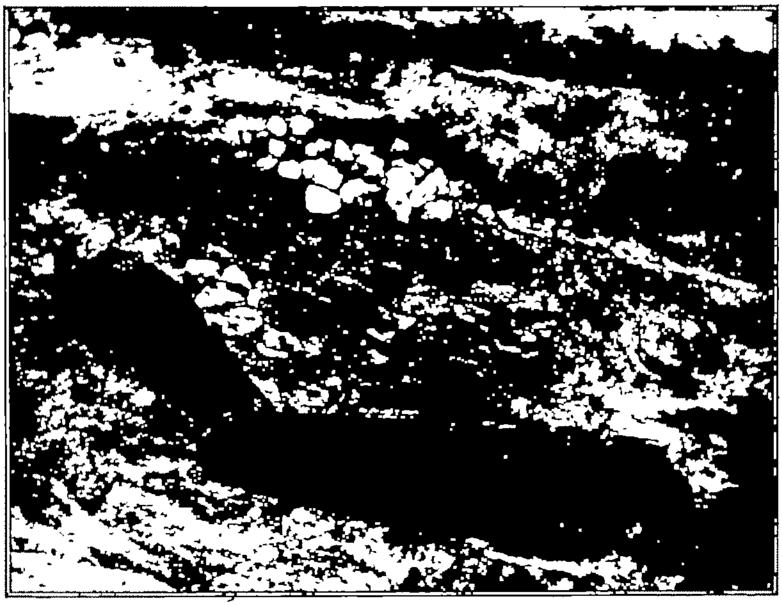

FIG. 1.—Remains of wooden structure *in situ* in the lower floor in Messrs. Bolton and Co.'s brickfield, Ipswich.

The artefacts mentioned are in every way comparable with others found in the lower floor in the immediately surrounding area and throughout the brickfield, and the wooden structure described was buried beneath (1) surface humus, 4 inches; (2) reddish sand with small ferruginous concretions, to 18 inches; (3) greyish sand, vaguely stratified, to 2 feet 6 inches; and (4) black, peaty sand, to 1 foot (this sand is evidently the lower part of layer 3). These strata appeared to be quite unbroken, and, with the exception of the humus, to be continued into the neighbouring escarpment, where the level at which the structure rested is covered by about 13 feet of deposits.

Fig. 2 shows the condition of the strata overlying the wooden structure before it was completely uncovered. As will be seen from Fig. 1, there was no trace of a continuation of the habitation to the east, and my present opinion is that it represents all that remains of a primitive shelter of some kind. But I admit, frankly, that I have never seen any structure of this kind before, and I have no wish to be in any way dogmatic as to its original form, or use.

The flint implements, together with a series of specimens made from non-flint rocks, found in the lower floor, were regarded by the late Prof. V. Commont, and other archæologists, among whom I am to be numbered, as referable to a phase of the Upper Mousterian, palæolithic, culture, but Prof. Henri Breuil, and several investigators, believe the specimens must be assigned to some early portion of the neolithic period. Further, though I have little doubt that the valley in which these ancient floors occur has been deepened since their occupation by man, and a considerable thickness of hill-washes of, apparently, different ages, deposited over these occupation levels, yet it is not, at present, possible to say with certainty to what particular time, after the deposition of the Upper Chalky Boulder Clay of the Ipswich district, these events are to be referred. The north-east portion of the brickfield where the wooden structure was found has been inhabited by rabbits for a very long period, and their activities have, in some cases, carried pieces of Roman bricks, and other objects, to a depth of many feet. The majority of the Roman remains of the area occurs, however, in, and just beneath, the surface soil, and though two small pieces (the presence of one of these may, probably, be accounted for by supposing it to have been thrown in with the material used to cover up the structure after discovery, so that it could be examined *in situ*, by other archæologists, before removal) of brick were found within a yard or two of the structure, and at a similar depth from the surface, I find it difficult to believe that the habitation itself is of Roman date, especially as the strata above it showed no signs of disturbance, as is so apparent in graves of this period in the high ground to the west.

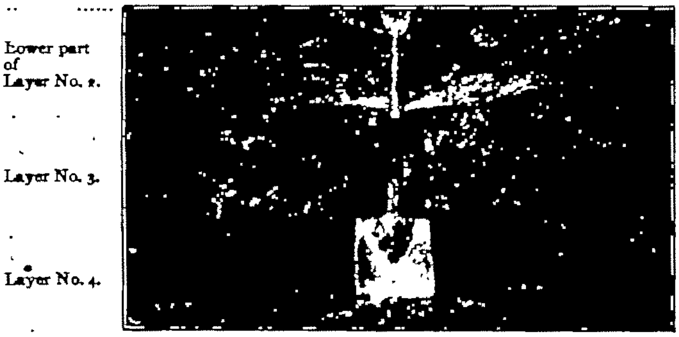

FIG. 2.—Section above wooden structure found in lower floor of Messrs. Bolton and Co.'s brickfield, Ipswich.

The site where the structure was found is now completely water-logged, and there is no doubt that this condition accounts for the preservation of the wood, which, however, has had to be kept immersed in a suitable liquid to prevent its disintegration. This work has been undertaken by Mr. Guy Maynard, curator of Ipswich Museum, who also took the excellent photograph showing the structure *in situ*. About 15 yards to the west of where the discovery of the habitation was made, traces of what appeared to be another were found; only in this case a portion of one of the stakes, and some small branches, were alone preserved. The condition of the wood found, which, by experiments I have carried out, could, I believe, have been shaped by a sharp flint, and split off a trunk by means of wedges of stone, though, of such widely different antiquity, exhibits a similar appearance to many of the branches and other parts of trees found in the Cromer Forest Bed of Norfolk.

At a later date I hope to publish a fully illustrated and detailed account of this discovery.

J. REID MOIR.

Ipswich.

The Solar Constant and Terrestrial Magnetism.

A LETTER in NATURE, November 28, p. 785, under the above title by Dr. G. C. Abbot, discusses a recent paper of mine in the *Proceedings of the Royal Society*. It refers to two of the subjects investigated in my paper, the 27-day interval, and the relation between corresponding daily values of S (the solar constant), as published by Dr. Abbot, and of C, the international character figure, intended to supply a measure of magnetic disturbance. To take the second question first, Dr. Abbot's statement is as follows: "Dr. Chree does find indications of magnetic disturbance associated with low values of the solar constant. Inasmuch as higher solar constant values are generally associated with numerous sunspots and abundant magnetic disturbances, he thinks this paradoxical finding of low solar constants associated with magnetic disturbances is non-significant. On the contrary, it is exactly what we should expect . . . the passage of an individual sunspot group over the central meridian of the solar disc is almost always associated with decreased values of the solar constant, and doubtless frequently with terrestrial magnetic disturbances. Hence it is prevailingly with low rather than high solar constant values that individual magnetic disturbances will be found associated."

What I actually did was to take for each month of 1923 the 5 days of largest S and the 5 days of smallest S. This supplied 60 days representative of high and 60 representative of low solar constant. Calling the representative day in either class n, I calculated from the De Bilt annual table the mean value of the magnetic character C for day n and the associated 4 subsequent days. The results were as follows, A denoting the group in which n was the representative day of high S, and B the group in which n was the representative day of low S.

VALUE OF C.

Day.	n.	$n+1$.	$n+2$.	$n+3$	$n+4$.
A	0·39	0·49	0·48	0·46	0·47
B	0·50	0·51	0·57	0·60	0·55

The mean value of C for 1923 was 0·48.

Dr. Abbot's explanation does not seem to me at all to fit the facts, even if for a moment we accepted them as exact physical data. What it should lead to would surely be a decided excess in C in the day n of group B over the mean value for the year. Now the excess is only 0·02, and no one, I should think, who knows anything of magnetic character figures would accept this as significant. If any of the figures are significant, it is the low value of C in day n of group A, and the high values of C on days $n+2$ and $n+3$ of group *B*. But on these figures Dr. Abbot's explanation seems to throw no light whatever.

The results did not encourage me at the time to prosecute the inquiry further. But in view of the weight naturally attaching to Dr. Abbot's views, I have now extended the investigation to 1921, 1922 and 1924, so as to cover the four years for which Dr. Abbot claims the highest accuracy in the values of *S*.

If the cause suggested by Dr. Abbot were sensible in 1923, the year of sunspot minimum, we should expect it to be conspicuous in the other three years, which had on the average a sunspot frequency more than three times as large. The results are given in the following table, *A* and *B* distinguishing the two groups of days of high and low solar constant as before. Instead, however, of the absolute values of *C*, I give in each case the algebraic difference from the corresponding mean from all days. Only 11 months were available for 1924, but as much weight has been allowed to this year as to the others. The mean character figure for the four years combined was 0·575.

VALUE OF *C*.

	Day	*n*.	*n*+1	*n*+2	*n*+3	*n*+4.
A	1921	+0·05	+0·10	+0·03	−0·05	−0·03
	1922	+0·05	+0·05	−0·02	+0·02	−0·05
	1923	−0·09	+0·01	0·00	−0·02	−0·01
	1924	−0·02	+0·08	+0·12	+0·02	−0·05
	Mean	0·00	+0·06	+0·03	−0·01	−0·035
B	1921	+0·11	+0·07	+0·08	+0·08	−0·04
	1922	+0·01	−0·05	0·00	0·00	0·00
	1923	+0·02	+0·03	+0·09	+0·12	+0·08
	1924	−0·07	+0·01	+0·02	+0·04	+0·11
	Mean .	+0·02	+0·015	+0·05	+0·06	+0·04

There is no column in which the higher value of *C* does not appear in the group *A* days in at least one year out of the four. In column *n* it occurs in group *A* in two years, and in column *n* + 1 in three years. No column gives a larger mean value for *B* than column *n* + 1 gives for *A*. If we omitted 1923, the year of sunspot minimum, the mean value of *C* in column *n* would be higher for group *A* than for group *B*. It will, I trust, be generally admitted that my attitude towards the data of 1923 has been justified.

There is nothing perhaps in the results now obtained incompatible with Dr. Abbot's belief as to the screening effect on ordinary solar radiation of sunspots when over the central meridian. If, however, such screening has a sensible effect on the solar constant, the apparent absence of a 27-day interval in the values of *S* becomes increasingly strange. If this interval had been prominent in even a few months of the four years, the method which I employed for detecting it should not have led, as it did, to a wholly negative result. Dr. Abbot's comments on this result leave me in doubt whether he believes that the 27-day interval, while not exhibited by *S* in recent years, was a true phenomenon in the earlier years, *e.g.* 1915, when he recognised it. If the phenomenon were real, we should have expected it to be shown the more clearly the more accurate the observations. In the case of magnetic data, it has shown no tendency to become less prominent since 1915. Perhaps I may say frankly that one of my reasons for investigating the matter was that I felt that my assurance that the apparent day-to-day fluctuations in *S* represented real fluctuations in the sun would be materially strengthened if they exhibited the 27-day interval clearly.

C. CHREE.

December 11.

Passivity, Catalytic Action, and other Phenomena.

THE writer's view of the passivity of chromium, manganese, iron, cobalt and nickel (NATURE, March 28, 1925, 115, p. 455) may now be extended and correlated with the recent work of H. S. Taylor (*Proc. Roy. Soc.*, 1925, A, 108, p. 105) and of E. F. Armstrong and T. P. Hilditch (*ibid.*, p. 111) on catalytic action at the surface of nickel, with that of J. Heyrovský (*Rec. trav. chim.*, 1925, 44, p. 499) on overvoltage, and with that of T. M. Lowry on the nature of chemical action. This view is based on Bohr's distribution of electrons within the atom. It supposes that in the elements mentioned the number of electrons in the outermost orbit is "ideally" between one and two, and is therefore either one or two, and that in consequence the atoms of such elements can never be electrically neutral in the same sense as atoms of sodium or of zinc. The experimental evidence favours calling the state with one electron in the outer orbit passive, and that with two electrons in the outer orbit active. The difference in potential between the two states of each of these metals is about 1 volt.

This Jekyll and Hyde explanation of passivity appears to differ *in toto* from the ordinary view which ascribes passivity to a protective film. It leads to a simple explanation of the non-corrosion of stainless steel. It is known that stainless steel is electrochemically nobler than copper. Now I find that both chromium and iron when passive lie between copper and bismuth in their susceptibility of being attacked by acids, although when active they are more reactive than cadmium. I find also that passive chromium and passive iron are closer in reactivity than are active chromium and active iron. I am less sure, although I have some experimental evidence in favour, that both iron and chromium when in true solution in a second metal become passive. It is known that chromium and iron are in solid solution in stainless steel. Each therefore may be regarded as passifying the other. It follows from what has been said that stainless steel should act like a nearly homogeneous metal which is nobler than copper, and this is what it is known to do.

It is known that some of the metals of the palladium and platinum groups and of the metals with "coloured ions," titanium, vanadium, chromium, manganese, iron, cobalt, nickel, copper, niobium, molybdenum, tungsten and uranium differ remarkably from other metals in their power of adsorbing certain gases and catalysing gaseous reactions. If the physicists will grant that atoms of these metals may conduct an electron from one reacting molecule to another, it is possible from a chemist's point of view to relate adsorption and catalytic action with passivity.

(*a*) I regard the metals mentioned above as being potentially able to exist in both active and passive forms, one of which is stable; thus manganese and iron are normally in the active form, and nickel and platinum in the passive form.

(*b*) I think these metals are best able to adsorb gases and to act as catalysts when in the passive form.

(*c*) They adsorb, because of their property of never being electrically neutral, a molecule which is capable of exhibiting polarity, the negative part of the molecule being attracted to the outside and the positive to the inside of the atom.

(*d*) They catalyse a reaction between A_2 and B, where A represents an atom, and A_2 and B molecules, because of their potentiality of passing from the passive to the active form. This may occur when the outer orbit gains an electron from A_2 or B and the inner orbit expels one on to B or A_2 (as well as in the normal way by gaining an electron from an inner orbit) so that the reaction may go

$$A_2 + B \longrightarrow A_2^+ + B^- \longrightarrow A_2B,$$

or $A_2 \longrightarrow A + A$, followed by $A + B \longrightarrow AB$;

the active form of the catalysing atom then reverts to the passive, either spontaneously or as a result of either final reaction. In other words, my view is that the reaction takes place because the passage of an electron from A_2 to B activates both, and that the catalysing atom is the conductor of this electron.

An example will illustrate. When metallic cadmium is shaken with dilute sulphuric acid, some of its atoms expel electrons to form ions, and in so doing discharge hydrogen ions to form atoms of hydrogen on the metallic surface. The chemical activity of these atoms is a simple function of the reactivity of the cadmium. These atoms are known to combine very slowly with each other, and this is expressed by saying that cadmium has a high hydrogen overvoltage. If a little platinum, tungsten or molybdenum be deposited on the cadmium, combination of the atomic hydrogen proceeds rapidly, and these metals are said to have a very low overvoltage. The view expressed in (*d*) shows how this occurs, and explains why the metals which exhibit passivity alone have very low overvoltages In this case the reactions are

$$H + H \longrightarrow H^+ + H^- \longrightarrow H_2.$$

This is in accord with recent work by J. Heyrovský on the dropping mercury electrode, who shows that the passage from atomic to molecular hydrogen is better represented by the changes $2H \longrightarrow H^+ + H^- \longrightarrow H_2$ than by the change $2H \longrightarrow H_2$.

These views also carry those of H. S. Taylor, E. F. Armstrong and T. P. Hilditch on one hand, and those of I. Langmuir on the other, a definite step further. The former think that in a hydrogenation process at the surface of nickel, both reactants are attached to a single atom of nickel; the latter thinks that the reactants are adsorbed on adjacent atoms. In both cases the adsorption of the reactants is explained by the fact that nickel is not electrically neutral in the same sense as is zinc, and, in the first case, the subsequent reaction is explained by the mechanism given in (*d*) above, namely,

$$A_2 + B \longrightarrow A_2^+ + B^- \longrightarrow A_2B.$$

Since the passage from the passive to the active form involves the expulsion of an electron from an inner orbit, it is possible that when this change occurs in the presence of an adsorbed molecule, this molecule will be split into atoms, $A_2 \longrightarrow A + A$. This suggests an explanation for the well-known but unexplained observation that gases adsorbed on nickel, platinum, palladium, etc., are sometimes in the atomic condition. When a second molecule B comes sufficiently near to this atom and is capable of reacting with it, the reaction $A + B \longrightarrow AB$ occurs as I. Langmuir thinks.

A. S. RUSSELL.

Weather Prediction from Observations of Cloudlets.

MAY I refer to the first letter of Sir G. Archdall Reid? (NATURE, November 7, p. 676). He says: "If then the behaviour of the smallest and thinnest fragment of cloud that can be clearly isolated be watched, it is usually possible to predict very quickly and with fair confidence the state of the weather for the next few hours. If the cloudlet waxes visibly, rain is almost certain; if it wanes, fine weather is equally probable; if it neither waxes nor wanes, existing conditions are likely to continue." It seems to me that the method of forecasting is falsified on every day on which clouds form and when rain does not follow, and there are very many such days in the year, for the cumulus of a fine day, which is common in spring, summer, and autumn, and occurs sometimes in winter, begins its life as a cloudlet, whether the ordinary man gets up early enough to see it or not. Certainly, too, cirro-cumulus often begins its life as cloudlets, but I have never seen cumuli "wane into cirro-cumuli" and rather doubt whether any one has ever observed such a phenomenon.

I do not think that Sir Archdall Reid quite appreciates my point about cirro-cumulus: we often see cloudlets of this variety waxing in one place and simultaneously waning in another, are we to predict rain from the waxing, or fine weather from the waning cloudlets, when both prognostics are occurring at one and the same time? Lenticular cirro-cumulus is composed of cloudlets that are born on the windward side and die in the leeward side of the cloud mass; in his first letter Sir Archdall Reid gives two possible explanations of this phenomenon; I should like to mention that it was these explanations to which I referred, and not any explanation of his main thesis, for as he says he gave none.

I quite agree that the waxing of cloudlets is often followed by rain, for we cannot have rain without cloud, but I think that it is just as often not followed by rain, and I certainly cannot think that if cloudlets wax visibly "rain is almost certain," for if this were the case we should have scarcely any rainless summer days. But Sir Archdall Reid seems less certain about the method in his second letter (December 12, p. 864) than he was in his first. I may be mistaken, but it seems to me that the method is scarcely of more use than the tossing of a coin; but, on the other hand, I am not sure that I understand the second of Sir Archdall Reid's definitions of cloudlets—"small and diaphanous clouds which can be seen at the same time in every part," and it is possible that our disagreement is based on our definitions of cloudlets. It would be interesting to know what those who are more familiar with forecasting than I am think of the question.

C. J. P. CAVE.

Stoner Hill, Petersfield,
December 22.

THE correspondence on this subject in recent issues of NATURE has been of particular interest to me, because the observation of the waxing and waning of cloudlets has been made by me for the last four months in trying to forecast for the next few hours the probability of clear or cloudy weather. I may add that these observations have always been made about half-an-hour or so before sunset, for the following reason:

I have set myself the task of photographing the spectrum of a certain star on every fine night for a period of about 130 days, and I began this work on the night of September 9. The most convenient time for photographing this star is as soon after sunset as possible, when it is sufficiently dark.

As I have to go down 400 feet to get home, I prefer not to leave the observatory if the early evening is going to be fine.

On doubtful afternoons, therefore, I have studied the cloudlets, picking out the smallest and watching its behaviour. I have found that, in nearly every case, the waning cloudlet has given me for the next few hours clear weather. On the other hand, when the cloudlet increased in size I was nearly always doomed to a cloudy evening.

I have found, therefore, that this method is very successful at about the time of sunset, but have made no observations at other times of the day to test its value then. It has been most useful to me and saved me a great amount of unnecessary exertion.

On a New Porphyrin.

CHLOROCRUORIN is the name given in 1867 by Sir Ray Lankester to a pigment, red in concentrated solution, green dilute, dissolved in the blood plasma of Serpulid, Sabellid and Chlorhæmid polychæte worms. It has been shown (Fox, *Proc. Roy. Soc.*, in the press) that the chlorocruorin molecule is constructed on the same model as that of hæmoglobin. Oxy- and reduced chlorocruorin resemble oxy- and reduced hæmoglobin spectroscopically, with the corresponding bands moved to the red in the case of chlorocruorin. In a like manner, the derivatives of chlorocruorin which correspond to hæmochromogen, hæmatin and hæmatoporphyrin resemble these substances, with the same shift of the bands to the red.

There exists a family of pigments related to hæmoglobin. These are cytochrome, a complex of hæmochromogens present in most animal and many plant cells (Keilin, *Proc. Roy. Soc.*, B, vol. 98, 1925, p. 312); heliocorubin, a hæmochromogen in the gut of snails; and actiniohæmatin, in sea-anemones. Now, hæmoglobin, part of the cytochrome complex, heliocorubin, and actiniohæmatin all contain one and the same hæmatin nucleus (Anson and Mirsky, *Journ. Physiol.*, vol. 60, 1925, p. 161). Chlorocruorin, however, resembles hæmoglobin more closely in structure than do the other members of the hæmoglobin family which have just been referred to. Nevertheless, chlorocruorin does not contain the same hæmatin nucleus as these other pigments (Fox, *loc. cit.*). The reason for the difference existing between the hæmatin of hæmoglobin and that of chlorocruorin is that, whereas both contain iron, the former hæmatin has a different porphyrin from the latter.

This can be shown by treating both by Nencki's procedure for the preparation of hæmatoporphyrin.[1] Diluted Spirographis blood was extracted with acetic acid (1 part) plus ether (3 parts). The acetic acid was washed out with water, and the remaining ether solution of chlorocruorohæmatin was evaporated to dryness. The residue (with some sodium sulphite, to prevent oxidation of the porphyrin) was dissolved in hydrobromic-acetic acid. The porphyrin was driven by sodium acetate into ether and then taken back into hydrochloric acid (1 part HCl plus 2 parts water). Hæmatoporphyrin for comparison was prepared from hæmin with hydrobromic-acetic acid. The axes of the bands of the two porphyrins (both in HCl, 1 in 3) measured with Hartridge's reversion spectrometer (*Journ. Physiol.*, vol. 44, 1912, p. 1, and vol. 57, 1922, p. 47) were as follows:

Nencki's hæmatoporphyrin . .	593	549
Chlorocruoroporphyrin (Nencki's method)	613	553

H. Fischer and O. Schumm (*Zeit. Physiol. Ch.*, numerous publications in recent years) have added much to our knowledge of porphyrins. They show that porphyrins fall into two groups.

Group I. comprises porphyrins insoluble in chloroform. It contains (1) Coproporphyrin, extracted from human fæces and from yeast by ether-acetic acid, and (2) Uroporphyrin, found in pathological urine. Coproporphyrin is the porphyrin derived from a part of cytochrome (Keilin, *loc. cit.*). Cytochrome is present in relatively considerable amounts in yeast and in bacteria. Cytochrome (in yeast) gives in addition a porphyrin of Group II.

Group II. is formed by porphyrins soluble in chloroform and having the bands to the red of those of Group I. It contains (1) the porphyrin prepared from reduced hæmoglobin in whole blood by the action of HCl (Laidlaw, *Journ. Physiol.*, vol. 31, 1904, p. 467); (2) Kämmerer's porphyrin, extracted from putrefying blood by ether-acetic; (3) Papendieck's porphyrin, obtainable from fæces after a meat meal; and (4) Ooporphyrin, extracted by HCl from egg-shells.

The following table shows the wave-lengths of the band-axes of the principal of these prophyrins:

Porphyrin.	Reference.	Axes of Bands in μμ.					
		In Ether.				In 25 per cent. HCl.	
GROUP I.:							
Coproporphyrin . .	Fischer and Schneller, *Z.P.C.*, vol. 130	624	571	528	499	594	553
Ditto	Schumm, *Z P.C.*, vol. 136	623	569	526	495	593	550
GROUP II.:							
Laidlaw's porphyrin .	Schumm, *Z.P.C.*, vol. 132	631	575	535	502	602	557
Kämmerer's porphyrin .	Fischer and Schneller, *Z.P.C.*, vol. 130	633	575	533	498	602	557
Ooporphyrin . . .	Fischer and Kögl, *Z.P.C.*, vol. 131	631	581	537	502	603	557

I next submitted chlorocruorin to a modification of Laidlaw's procedure for porphyrin preparation. Spirographis blood was treated with acetic-ether. The resulting chlorocruorohæmatin was taken into sodium carbonate solution and reduced with hydrosulphite. In a current of carbon dioxide, concentrated hydrochloric acid was then added. For comparison (1) the porphyrin from hæmin was prepared by a similar modification of Laidlaw's method, and (2) ooporphyrin was extracted from egg-shells with hydrochloric acid. The measurements of the bands with Hartridge's spectrometer are given below:

	Axes of Bands in μμ.					
	In Ether.				In 1 part conc. HCl + 2 parts Water	
Porphyrin from hæmin	632	585	536	503	600	555
Ooporphyrin .	634	587	536	504	601	556
Porphyrin from chlorocruorohæmatin	641	580	553	512	614	559

It is seen that the bands of the porphyrin from chlorocruorin are situated considerably to the red of those of any of the above-mentioned porphyrins. This new porphyrin resembles the members of Group II. in being soluble in chloroform.

---

[1] I am indebted to Mr. R. Hill, of the Biochemical Laboratory, Cambridge, for valuable help.

If the composition of the porphyrin of chlorocruorin is ascertained, valuable light may be thrown on the peculiar metabolic process by which a few annelids synthesise chlorocruorin while so many animals build up hæmoglobin

Blindness of Cave-Animals.

I DOUBT whether Sir Ray Lankester would maintain his theory of the origin of blindness in cave-animals, at least in the fishes living in the North American limestone caves, if he had carefully considered the observations on these fishes published by Eigenmann and other American zoologists. There are two points of special significance in relation to the question of selection by the escape from the caves of individuals with better developed eyes, versus direct influence of darkness on the eyes The first is to what degree the actual ontogeny of the eye shows recapitulation, the second whether the individuals with power of vision would actually swim away from the darkness towards the light

Amblyopsis spelæus, the most abundant of the blind fishes of the caves of central North America, reaches a maximum length of 13·5 cm. It is placed in a small family closely allied to the Cyprinodontidæ. This family includes five other species occurring in the same or contiguous regions. Three of these, *Chologaster agassizii*, *Typhlichthys subterraneus*, and *Troglichthys rosæ*, also live in subterranean streams in total darkness. Two of them, *Chologaster cornutus* and *C. papilliferus*, live exclusively in streams and swamps on the surface of the earth.

If we consider the eye of Amblyopsis as the example of the subterranean species which has been most thoroughly examined, the organ is visible as a minute black spot on each side in specimens 35 mm. long Microscopically examined, it is very degenerate The lens is very small and displaced, or entirely absent. The vitreous humour has disappeared, the remnants of the retina form an irregular mass in the cavity of the eye, the optic nerve can be recognised where it leaves the eye but cannot be traced to the brain. After the mature stage of the fish the eye undergoes further progressive degeneration.

With regard to recapitulation, the lens and optic vesicle develop in the embryo at the normal stage and in the normal manner, but soon begin to degenerate. The optic nerve also develops normally in the embryo. Defects due to mutation do not usually follow a normal initial development.

In *Chologaster agassizii*, which is also completely subterranean, the eye is normal in structure, and functional, but reduced in size The fact that there are two other species of the same genus which live in daylight shows that this one cannot have been confined to darkness so long as the subterranean genera in which the eyes are degenerate and vestigial. If Sir Ray Lankester's theory were true, *C. agassizii* would not be in darkness at all but would have found its way out to the light. But it is probable that the instinct of all the species of Chologaster is not to seek the light but to avoid it. Eigenmann actually observed this in *C. papilliferus*, which is found under stones in the "springs" or small streams of south-western Illinois: the fish are negatively heliotropic, or photophobic He found that this was equally true of Amblyopsis and Typhlichthys, which, notwithstanding their blindness, have retained the habit of hiding under stones and the ledges of rocks. In Chologaster there is evidence that the reduction of the eye has commenced in association with its photophobic habits without confinement to total darkness. In a specimen of Zygonectes, one of the Cyprinodontidæ, 38 mm in total length, the eye was 2 mm. in diameter In *Chologaster papilliferus*, 32 mm. in total length, the diameter of the eye was 0·83 mm. In *C. cornutus*, 32 mm. in total length, diameter of eye 0·96 mm. In *C. agassizii*, the subterranean species, 39 mm. in total length, diameter of eye 0·72 mm

Lastly, it may be mentioned that in *Typhlogobius californiensis*, the eyes in the adult are minute and degenerate and almost if not quite insensitive to light This fish lives in holes under stones, which it never quits. It can scarcely be maintained that it remains in dark holes because defects in vision make it unable to find its way out, especially as in the young state its eyes are visible and apparently functional.

Heterochromosomes and Polyploidy.

DURING recent cytological investigations in the Salicaceæ, undertaken to demonstrate the presence or absence of sex- or heterochromosomes in certain species of Salix, I have discovered such chromosomes in the males of *Salix lucida* Muhl., *S. aurita* L., *S. cinerea* L., and *S. Andersoniana* Sm. Of these species, *S. lucida*, an American form, belongs to the section Pentandræ of the supersection Pleiandræ, *S. aurita* and *S. cinerea* to the Capreæ group of the Diandræ, and *S Andersoniana* to the Phylicifoliæ of the same supersection; all are, of course, diœcious. Of the polyploid series developed in Salix, *S. lucida*, *S. aurita* and *S cinerea* are tetraploids, and *S. Andersoniana* hexaploid

In the case of *S. lucida*, the heterochromosomes are easily discernible both in profile views of the heterotypical spindle in pollen mother cells and also in diakinetic figures. On the contrary, owing to the intimate relations between the paired chromosomes during diakinesis in *S. aurita*, *S. cinerea* and *S. Andersoniana*, they are not so readily recognisable at that stage in those species but stand out very clearly in heterotype metaphase side views.

In all four species, the larger member of the pair is more or less broadly (and occasionally obliquely) pear-shaped whilst the smaller is spherical, they lie on the periphery of the equatorial plate.

Although the mere demonstration of heterochromosomes in these species is in itself important, of even greater value is the light thrown on the development of polyploid series in plant genera. No matter what explanations are given of the origin of tetraploid species they all amount to the same in the end: whether we invoke chromosome division in the fertilised egg followed by a suspended mitosis, or any of the other theoretical explanations now current, in all there is implied a duplication of chromosome complement. Therefore, in diœcious plants possessing heterochromosomes, amongst the chromosomes so duplicated should be those chromosomes themselves, so that in the heterotype division of tetraploid species we ought to be able to detect two pairs of heterochromosomes and in hexaploids three pairs. However, careful examination has shown that in diploid, tetraploid and hexaploid alike only one pair is present. Hence, the problem of polyploid series in the Salices, and presumably in other genera, cannot have the simple solutions previously propounded, and the whole matter is thrown open for further consideration.

Coal Conservation and the Gas Industry.[1]

By Prof. J. W. COBB, C.B.E., The University, Leeds.

NOTHING has contributed more to the material advancement of civilised man from the state of his primitive ancestors than the utilisation of fuel for the production of light, heat, and power. Primitive man depended on the solar hear available from day to day, and his life was circumscribed accordingly. In temperate zones like our own, the sun's rays are too feeble and uncertain to enable us to obtain from them by direct means any considerable quantity of useful power, though in certain sunny regions, such as Egypt and California, it has been attempted. Even there, the amount and the cost of the plant for the production of the unit of power was excessive when compared with methods based on the use of fuel.

Vegetation, however, is capable of absorbing and storing up the radiant energy of the sun in the formation of organic compounds, which the plant is able to build up from carbon dioxide and water. In this way enormous quantities of fuel have been and are produced, by the combustion of which we are able to utilise indirectly the radiant energy of the sun absorbed by the plant in its synthetic processes. Man is, however, too impatient now to provide his fuel supplies by tree culture from one century to another, even were the necessary land available, while similar reasons rule out the cultivation of annual fuel crops in a crowded country such as Britain, where food crops must take precedence.

In default of fuel cultivation, we are compelled to rely on the accumulated store of fossilised vegetation in one or other of its existing forms. If we examine a table (below) showing the composition of dry, ashless fuels, we see that the individual analyses show a gradual concentration of carbon at the expense of hydrogen and oxygen, so that we pass over from a substance such as dry wood or cellulose (a principal plant constituent) containing less than 50 per cent. of carbon to coals containing 80-90 per cent. and even more when anthracitic—a process which has been imitated in the laboratory, particularly in the experiments of Bergius. Accompanying this concentration of carbon is the production of a substance in which the heat energy is more concentrated, in fact a higher grade and more useful fuel. Thus 1 lb. of coal on completed combustion develops about double the amount of heat obtainable from 1 lb. of wood or cellulose, and this increases the difficulty of basing our fuel supplies on "fuel crops." The position is made worse by the fact that wood, even when air dried, contains 15-20 per cent. of moisture, and the heating value is correspondingly lessened.

	Carbon	Hydrogen	Oxygen and Nitrogen.
Cellulose ($C_6H_{10}O_5$)	44·5	6·2	49·5
Wood . . .	50·0	6 0	44·0
Peat substance .	50–64	4 5-6·8	28–44
Lignites . .	60-70	5·0	20-35
Bituminous coals .	75-90	4·5-5·5	5·5-15·0
Anthracites . .	90–95	2-4	3

In peat the concentration of carbon has begun, but the peat when freshly cut contains 80-90 per cent. of water—as much water as milk—and to make it useful as a fuel the moisture content has to be reduced to about 25 per cent. The bulkiness of peat, the problem of drying it, and its low heating value when dry, limit its value as a fuel greatly. A high nitrogen content is a point in its favour when conditions allow recovery of by-products.

Lignite is a more concentrated fuel than peat, but its moisture content may still reach 40-60 per cent. Its heating value remains low, but by drying, briquetting, and by carbonisation this fuel can often be turned to good account. It occurs usually at or near the surface and is won by mechanical excavation rather than underground mining. It is available, therefore, at the pit at a very low cost, and much of the German electric power supply is based on lignite. Abundant deposits occur and are being developed in Canada and Australia, but in Britain supplies are negligible.

The net result of this survey is to show that we in Great Britain are dependent almost exclusively on coal—a fossil fuel, a wasting asset—for the possibility of many manufacturing activities and amenities of life. The known deposits of coal in this country will suffice to meet the present rate of consumption for a long time, and improved mining technique has made available coal which a generation ago would have been thought unworkable. On the other hand, the cost of coal has increased, and coal forms a large part of the cost of producing some manufactured products such as iron and steel, on which in turn the engineering industry depends. As compared with other countries we shall, therefore, be at a disadvantage as soon as coal becomes difficult or expensive to get, even though we can get it at a price. Another consideration is the tendency to substitute mechanical appliances for hand labour, which tends to increase the consumption of coal, unless the efficiency of its utilisation can be correspondingly increased.

In considering the complete utilisation of coal, one must not overlook its potentialities as a source of chemical products. In the plant we have not only a cellulosic skeleton but also juices and spores containing resinous substances, and their degradation products form the two main types of components found in coal. It is the resinous bodies which cause many coals to fuse on heating and to evolve much gas, burning with a luminous smoky flame. It is owing to the absence of such components that anthracites burn smokelessly.

Coal when consumed in an ordinary grate goes through two stages. In the first is evolved the volatile matter, which if cooled and collected is found to consist of gas, a sticky oily liquid, tar, and a watery ammoniacal liquor. The porous solid residue, consisting mainly of "fixed" carbon with the ash of the coal, is known as coke.

The second stage of burning coal consists in the combination with oxygen of the air of both the volatile matter and the fixed carbon of the coke. In the domestic fire it is attempted to carry both processes on together. This has a certain advantage of simplicity but is unsatisfactory in other respects. Smoke cannot be avoided, especially when fresh coal is added to the fire, for the two stages of combustion can scarcely be kept in step, and incompletely burned tarry matter escapes up the chimney producing smoke. Such fires have a low efficiency. Only 20-25 per cent. of the heat of the coal is radiated into the room, while attendance to a fire involves labour and dirt.

---

[1] From a paper, entitled "The Conservation of the Nation's Store of Solar Energy," read at the Conference of the British Commercial Gas Association at Plymouth, October 21, 1925.

The use of electricity instead, generated from the coal, has obvious attractions, but however efficiently it may be applied in the home, it must always be remembered that it carries on an average 10 per cent. and at best 20 per cent. only of the original heat of the coal. This 80-90 per cent. initial loss is too severe a handicap and entails an enormous waste of heat, though not apparent to the consumer. It seems to debar the use of electricity as a general domestic fuel.

An effective and logical remedy widely applicable consists in the initial carbonisation of the coal whereby the volatile matter is separated from the fixed carbon, as is done in the gas-works. In this way the coal can be resolved into a solid fuel—coke—a liquid fuel—tar (and motor spirit)—and a clean gas, all of which can be burned smokelessly and for most purposes more efficiently than coal. (The tar, though capable of serving as a fuel, has actually a greater value as a source of chemical products.) At the same time ammonia is recovered from the coal. This process of carbonisation, as carried out daily in the gas-works, does not waste the heat of the coal. The table below shows the fate of the heat units in the original coal after being subjected to carbonisation. The figures show the results of a year's working of a typical gas-works, not of the most modern type.

Carbonising Gas Coal in Horizontal Retorts.

Heat of combustion of coal	100·0
Heat content:	
Gas	22·5
Coke sold	48·3
Tar	6·0
	76·8
Heat used and lost in manufacture	23·2
	100·0

The heat units in the total coke made would be higher than the 48·3 per cent. shown, but some of the coke has been used for heating the retorts. Altogether, 23·2 per cent. of the heat of the coal has been used and lost in the process, leaving 76·8 per cent. in the products of carbonisation. This figure is termed the thermal efficiency of carbonisation. With more modern plant 80 per cent. would be a more representative figure. It is interesting to inquire what advantage is gained by carbonisation to compensate for the thermal and monetary cost of the process. From the watery product—ammoniacal liquor—is readily obtained ammonium sulphate, a valuable nitrogenous fertiliser. The tar is the raw material of a great industry. By suitable treatment it furnishes benzene and toluene, which were found so indispensable as the basis of manufacture of high explosives. From them and other tar constituents are derived numerous colouring matters, drugs, and disinfectants. The lighter tar fractions gain increasing importance as motor spirit, and the heavier constituents as a material for the construction of roads suited to the demands of modern traffic. Certain creosote oil fractions are valuable as preservatives of timber, or alternatively may be employed for the propulsion of ships. Coal-tar forms at present our most valuable source of home-produced liquid fuel, and its national importance needs no further emphasis. Clearly there is a considerable creation of value as a result of transforming the resinous constituents of coal into tar instead of allowing them to make smoke in the open grate.

Let us now consider the gas. Here reference must again be made to thermal efficiency, because it is so important in this connexion. The open fire is the most favoured method of heating rooms in our houses, and is, in my opinion, likely to remain so, whatever fuel may emerge in time as being the most satisfactory for burning in it. The peculiar value of radiant heat as thrown out from a fire has been appreciated by generations of our countrymen, and recent physiological work has shown that this peculiar excellence was by no means imaginary, but had a sound scientific foundation. But when we use raw coal in an open fire, we pay a big price—too big a price in many ways—for its cheery blaze.

The inefficiency of the coal fire is best seen when one compares it with the gas fire. For every 100 heat units supplied to a modern gas fire, practically half is radiated into the room, while with a coal fire the radiated heat is less than a quarter of that supplied in the coal. In both these cases there is, of course, a proportion of heat which goes up the chimney. With the coal fire it is inordinately large, but with the gas fire it is reasonable in amount, about one-third of the total. I say it is reasonable in amount because a certain quantity of heat going into the chimney does perform a useful function in ventilating a room; and as the ventilating function of the open fire is probably as important as its heating function, a certain amount of heat may very well be devoted to this purpose. The trouble with the coal fire is that the proportion used in this way is much too large, wasting fuel, and over-ventilating the room to the extent of creating draughts. The gas fire is economical in the way in which it utilises the heat units brought by the gas for the combined purpose of heating and ventilating, which it does in an economical and practically convenient manner. It is sometimes said in extenuation of the very low thermal efficiency of electrical generation that the efficiency of an electrical heating appliance can be taken as 100 per cent. But plainly this can only be the case if no air goes into the chimney hot enough to produce the ventilation which is so essential, and in that case an auxiliary ventilating appliance must or should be provided, with additional cost.

This high efficiency of gas for room heating is typical of what it can do in many other uses, because it is so subject to simple and exact control that apparatus can be designed for burning gas of a much more refined and scientific construction than can be contemplated for the burning of coal. Moreover, not only is gas clean in the ordinary sense, but it also has been purified from nearly all its sulphur compounds at the gas-works, while it has to be remembered that every ton of raw coal which is burned in even the most modern steam-raising plant of a factory or electrical generating station turns out about half a hundredweight of sulphurous acids into the atmosphere. In this respect gas is superior not only to raw coal, but also to the smokeless solid fuels.

Nor is it to be forgotten in these days, when the electric motor has rightly come to occupy such a strong position for the provision of power, that the gas-engine is thermally more efficient than any other type of prime mover in common use, and that Sir Dugald Clerk has expressed the opinion only recently that, where a small isolated unit of power is required, a gas-engine using town gas is still the most economical plant available from both the thermal and the monetary points of view.

The solid smokeless fuel, or coke, resulting from carbonisation, is a subject to which the public attention has been very much directed lately by numerous utterances—æsthetic, hygienic, scientific, technical, and political—displaying very varying degrees of competence and impartiality. It may, however, be taken as agreed that for those domestic purposes where solid fuel continues for any reason to be used, it should be of the smokeless kind. There is no chance of our attaining the ideal of the smokeless city until that principle is applied.

The coke produced by the ordinary gas-works process is a form of solid smokeless fuel which is at the present time produced in large quantities. Other methods have been suggested and are being tried which have been grouped under the heading of low-temperature carbonisation.

Now it is to be remembered that in the earlier days of the gas industry, gas was made in iron retorts, which meant that of necessity lower temperatures were employed than are in common use to-day. The plain fact is that the development of the gas industry has proceeded in the direction of making more gas from the coal; and there is a sound reason for this, because every heat unit secured after the transformation of the carbonisation process in the form of gas is, from every point of view, thermal or monetary, worth so very much more than a heat unit in coal, and this appreciation in value is so much greater in the gas than it is in the tar or the coke.

The changes in gas practice have been in the direction of using higher temperatures, or even of gasifying some of the coke either in the gas retorts or in separate generators. The reversion to low-temperature carbonisation is not easy to justify. The carbonisation process has to be considered as a whole, as one yielding four main products—gas, tar, ammonia, and coke. Merely lowering the temperature gives very much less gas—say, about half. More tar is produced, not of a kind containing benzene or toluene, and more difficult to refine, but probably yielding more motor spirit. The ammonia yield is smaller. The coke is softer, easier of ignition than ordinary gas coke, and burns with more flame, but is more liable to crumble in manufacture and transport.

To counterbalance the loss of the high gas yield does appear to be an exceedingly difficult problem, as is now coming to be realised. I am far from saying that it is insoluble, but it would appear to necessitate either obtaining a very high order of value in the by-products, or of evolving some process of carbonisation very much less costly than has hitherto been used; and neither of these is the easy thing to do which optimistic utterances would suggest.

The production of smokeless solid fuel, however, is not necessarily bound up with low-temperature carbonisation. Low temperature is only one of the factors involved. The transmission of heat through coal during coking, the physical and chemical changes which occur, and the extent to which the carbonisation process can be speeded up and modified by proper preparation of the coal, all require exploration. The gas industry is becoming increasingly alive to the possibilities in this direction, to the necessity for thorough and systematic examination of all the factors operating in the carbonisation process, and an investigation of what can be done, for example, by proper preparation of the coal, which may involve washing, grinding, blending, and briquetting, or even the addition of some inorganic constituent, because, strange though it may seem, the presence of some of the ash constituents, such as oxide of iron, has been shown to exercise a marked influence on the coking process and the nature of the coke produced. The further control of the quality of coke and its supply in a form which is not crumbly, but easily ignited, burning cheerfully and not leaving too much ash, is one of the most interesting things with which the gas industry is now occupied.

I may, however, at this point indicate that undoubtedly the best utilisation of smokeless solid fuel will also be greatly helped by a more careful study of the best construction of grate for burning it, since the grate as at present used has been evolved for the burning of raw coal, the requirements of which are somewhat different. There is little doubt that, if the house grate of to-day was slightly, but suitably, modified in construction, quite a hard coke would burn well in it. As regards the efficiency obtainable from coke, all the tests made by Dr. Margaret Fishenden, on behalf of the Fuel Research Board, indicate that it is appreciably higher than that obtainable from raw coal (which is all to the good), though nothing like so high as that obtainable from a gas fire.

Enough has now been said to indicate clearly that, apart from other considerations such as those of cleanliness and hygiene, the gas industry is entitled to put forward the claim that, on the basis of thermal efficiency alone, its methods of dealing with our coal supplies represent the highest order of actual achievement in the present. What it may be able to do in the future it is not possible for any one of us to foresee. Its problems become more interesting every day, necessarily more complicated, and make more demands upon those engaged in it. But the position of the gas industry is scientifically sound; and by systematic and patient research and trained intelligence applying the results of research to technical and commercial developments, that position can be made even more assured.

Cosmic Rays.

By C. S. Wright.

THE recent address by Prof. Millikan, printed in NATURE of December 5, together with the popular statements in the daily press, have directed attention once more to certain geophysical problems which have received scant attention lately from British investigators Details of Millikan's observations on the top of Mount Whitney are still lacking, but it seems clear that another phase in the investigation may now be regarded as terminated.

The first phase of the investigation opened with the discovery in 1901, independently by C. T. R. Wilson and Geitel, that within a closed vessel there was a continuous production of gaseous ions which rendered the contained gas conducting to a minute extent. This observation was followed by the discovery, by Elster and Geitel, of the existence of radioactive products in the atmosphere which might be responsible for some part at least of the conductivity observed. Observations of the radioactivity of the air or, more correctly, measurements of the ionisation due to the active products collected on a negatively charged wire, led to the certainty that the products were due to the disintegration of radioactive emanations derived from the soil, springs, etc. A systematic investigation of the various types of rock by the present Lord Rayleigh soon yielded representative figures for their radium content, but it was not until 1908 that an accurate value for the mean radium content of the air near the ground (about 10^{-16} gm. per c.c.) was available as the result of the work of Eve, Satterly, and Ashman. These efforts made it clear that the radioactivity of earth, air, and—to a minute extent—water, must all be regarded as possible contributors to the ionisation in closed vessels.

In the meantime another plan of attack was developed in Canada in 1902 by Rutherford and Cooke, and McLennan and Burton, followed by Wright and others. This attack was directed towards localising the source of the penetrating radiation and determining its hardness or penetrability. Screens of lead were used by the first-named investigators, while McLennan and Burton, having found that the local water supply was free from radioactive impurity, surrounded their vessel with layers of water up to 60 cm. thick. Both experiments were successful in reducing the ionisation by about 30 per cent. Rutherford and Cooke increased the amount of lead in their screens to a total weight of 5 tons, but no greater decrease was observed than with a screen thickness of 3 cm. It was also found that the radiation in the basement of the laboratory in Montreal apparently came equally from all directions. In the attempt to reduce the ionisation further, and in the hope of localising its sources, Wright was driven in 1908 to undertake field observations over the surface of Lake Ontario, on frozen lakes, and in a deep tunnel at Niagara Falls. These experiments showed a notable reduction over the water and ice, but no reduction in the tunnel, and enabled an estimate to be made for the contribution of the earth to the measured ionisation. Though later work has thoroughly confirmed the efficacy of the water and ice-screens, an observation on the University tower at Toronto conflicted with observations by von Bergwitz, McLennan and Macallum, and Wulf, all of whom found a decreased ionisation at a height above the earth. This discrepancy may have been due to a local concentration of radioactive material at the place of observation.

In the interval a further line of attack had been opened by the discovery of a daily variation in the penetrating radiation by Campbell and Wood (1907), Strong, and Wulf, though these observations were flatly contradicted by those of Gockel, Wright, and Cline. This contradiction was later recognised as due to local variations in the relative importance of the different sources of ionisation. It was indeed not until 1909 that the relative importance of these various sources was realised with any certainty, and particularly the part played by that source which was chiefly responsible for the local daily variation in the penetrating radiation. This source was a surface deposit of radioactive materials derived from the air and resulting from radioactive emanations coming from the soil. These active materials are continually being deposited on the earth's surface at a rate dependent both on the varying value of the earth's potential field and upon the amount of active material in the atmosphere, while the normal rates of decay of the radioactive substances while in the air and on the ground set a limit to their accumulation.

This phase of the investigation may be regarded as closing with the determination in 1910 by Simpson and Wright, during the course of Capt. Scott's last Antarctic expedition, of the contribution to the ionisation by the radioactive surface deposit on the ship after immersion in land-derived breezes of measured radioactivity. The slow rate of decay of the ionisation, after the return to normal sea conditions of low-air activity, indicated the presence of thorium as well as radium products on the ship's structure. The absence of a daily variation during the voyage was clearly due to the continuous low activity of the ocean breezes.

These data, and those obtained by many others on land, showed that the chief recognised sources of penetrating radiation were the active surface deposit, radioactive substances in the earth, and active products derived from emanations which might enter the ionisation vessel if steps were not taken to exclude them. The effect of radioactive materials in sea-water, or ice, beneath, and in the atmosphere round and above, the place of observation were recognised as inappreciable. Even under the most favourable conditions, however, there remained still an ionisation about half as great as the minimum land value, and the source of this residual ionisation was still unknown at this date. Possibly the view that the residual effect was due to a slight radioactivity of all materials was the most popular one. One of the earliest investigations had, in fact, arisen from the discovery of lead as the end-product of the radium transformations, which led McLennan and others to the observation that the substance of the ionisation chamber, *e.g.* lead, may contribute notably to the conductivity. Though some samples of lead were clearly radioactive, no definite conclusion was reached on the question whether all substances were radioactive in some degree, or whether the differences with different metals were due to a secondary radiation from the walls of the container.

The second phase of the investigation may be said to commence with the initiation of measurements in balloons by Gockel and later by Hess, who established the fact that, during an ascent, there was first a decrease, and later an increase, in the measured ionisation. To explain this increase, Hess assumed the existence of a "sehr durchdringende Strahlung ausserterrestrischen Ursprungs," which was responsible even for a portion of the ionisation at sea-level. A similar increase with height was observed in balloon ascents over the sea. This work was continued by Kohlhörster during 1913 and 1914, with improved apparatus, the balloons ascending in one case to a height of 9 km., and an attempt was made to calculate the absorption coefficient of the radiation from the relation between height and ionisation. These results indicated, on the assumption that the radiation was directed vertically downward, that the hardness of these rays was about six times as great as the hardest known γ-rays. Radiation of this hardness would be able to penetrate through the atmosphere to sea-level in measurable amount. These results were confirmed by numerous German observations made on mountain tops. Kohlhörster,[1] in his 1923 paper, calculated the absorption coefficient of the cosmic rays from the later balloon observations and from screening experiments in water and in glacier ice. The absorption coefficients so obtained showed considerable consistency, and the average value was given as $\mu\,(\text{water}) = 2{\cdot}5 \times 10^{-3}$, *i.e.* the rays were found to be more penetrating even than the first upper-air observations showed. This absorption coefficient compares with $\mu\,(\text{water}) = 3{\cdot}9 \times 10^{-2}$ and $3{\cdot}3 \times 10^{-2}$ for the hard γ-rays of radium C and thorium D.

In the same paper, Kohlhörster discusses the source of the cosmic rays in the light of a variation observed by him during the day in a glacier crevasse, and even under 4·5 metres of glacier ice. He tentatively ascribed the variations to the changing orientation of the crevasse with respect to sources in the neighbourhood of the Milky Way. In fact, the tentative conclusion was in favour of an origin such as the red giant stars or nebulæ.

In the absence of detailed results, the observations of Millikan seem to confirm and also to extend those of Kohlhörster, though there is one point at least on which there is some disagreement. In addition to giving a new figure for the absorption coefficient—$\mu\,(\text{water}) = 1{\cdot}8 \times 10^{-3}$—corresponding to a greater hardness even than was thought, Millikan adds that the rays extend throughout a spectral region from 0·0004 Å.U. to 0·00067 Å.U., and that the secondary rays from the cosmic radiation show the Compton effect. From the wording of Prof. Millikan's address it seems that he has measured the difference in wave-length between the primary and secondary scattered rays. He states that the cosmic rays come into the earth with equal intensity at all hours of the day and with practically the same intensity in all directions. It is this conclusion which appears to be in disagreement with Kohlhörster's results, though it is true that the daily variation observed by the latter was not pronounced.

The minimum wave-length of the cosmic radiation quoted by Millikan is only $\frac{1}{10}$ that of the hardest known γ-rays of radioactive type, the wave-length being in fact of the order of the distance over which the positive charge of the atomic nucleus behaves as if it were a point charge. It is therefore difficult, as Millikan points out, to escape the conclusion that the rays arise from transformations actually in the nuclei of atoms. As to the origin of the cosmic rays, it is difficult to consider the possibility of their initiation except in certain portions of space where the existence of atoms stripped of all their electrons may be suspected, and where absorption of the rays near the source will not be excessive Some such considerations doubtless led Nernst to the view that the origin of the very penetrating radiation might lie in the nebulæ of low density.

The scattered radiation will, by virtue of the Compton effect noted by Millikan, bridge the gap between the cosmic rays and the gamma-rays from radioactive substances, but unless a method of producing these rays in the laboratory can be developed, the only possibility of experimenting effectively with them will be by observations at high altitudes. Lest it should be thought that these rays might fulfil the function of the "ultra-X" rays which Perrin has postulated as the possible cause of radioactive transformations, it is well to point out that early measurements of the ionisation in closed vessels in tunnels and in deep caves gave values which were sometimes as large as those made on the earth's surface above. As these results could only have been due to radioactivity of the rock forming the cave, it is clear that Perrin's postulate is not in any way rendered more probable by the existence of rays of the hardness noted.

While we may consider Millikan's fine achievement as terminating the second phase of the investigation, it seems certain that there are other developments to follow. It is possible that there is still some ionisation in closed vessels which is not accounted for, and for which a separate cause must be found. The lowest values obtained in a metal vessel over the sea correspond to the production of about 4 pairs of ions per c.c. per sec. Of this number, between one and two pairs seem to be due, directly and indirectly, to the cosmic rays. According to Kohlhörster the ionisation is greater by the production of 4, 9, and 17 pairs of ions at heights of 3, 4, and 5 km. above sea-level. A contribution of about 2 pairs may result from the surface deposit of radioactive materials on a small ship such as the *Terra Nova*, this being derived originally from land sources. An addition of 6 pairs or more is to be expected in land observations, in part due to radioactivity of the soil and in part to additional radioactive deposits on neighbouring surfaces. The effect of this deposit is equivalent to about 0·5 gm. of radium per sq. mile, on the average. The amount of this land contribution will of course vary with the site of the measurements, and one is probably not far wrong in estimating that, on the average, the land effect is due about equally to the two sources stated. An exceptionally low value of 2 6 pairs of ions was obtained by McLennan and Murray over Lake Ontario, using an ionisation chamber of ice, while observations in an ice cave on the shores of the Antarctic Continent gave a minimum value of 3 pairs, though too much reliance must not be placed on this figure. It is, however, known that the air radioactivity in this place is only slightly greater than over the ocean. Any residual ionisation which has not been accounted for is therefore minute in amount. The final results of Prof. Millikan's observations may settle this point, but the very slightest trace of radioactive impurity in or on the walls of the vessel would cause an ionisation sufficient easily to account for any difference. Measurements in a metal chamber under varying high pressures is one investigation which would probably give useful information on the residual effect, if made in a submerged submarine in order to exclude the cosmic rays.

---

[1] *Sitzungsber. d. Preuss. Akad. der Wiss.*, 34, 1923.

Though the ionisation currents dealt with in work on penetrating radiation are small—of the order 10^{-14} to 10^{-15} ampere—the measurements can be made with considerable accuracy, so that there is no possibility for doubt as to the reality of the existence of the cosmic rays. It is, however, a matter for regret that laboratory experiments on the properties of these rays cannot be carried out effectively in Great Britain, since it is only at great altitudes that the cosmic rays contribute more than a fraction of the total ionisation. The possibility of the discovery of a laboratory source of these rays must be regarded as remote, though it is unwise to be dogmatic even on this point.

Mineral Production in India.[1]

AMONG the many useful services rendered by the Geological Survey of India must be reckoned the issue of a Quinquennial Review of the Mineral Production, initiated during the directorship of Sir Thomas Holland. The first of these reviews appeared in 1905 (*Rec. Geol. Surv. India*, Vol. 32, Part I.), and covered the period 1898–1903. Since then, four others have been published, the latest, covering the period 1919–23, being a voluminous and interesting account of the progress during the period, contributed by the director (E. H. Pascoe) and the senior officers of the Survey, including L. L. Fermor, J. Coggin Brown, H. C. Jones, C. S. Fox, and W. A. K. Christie.

The average annual value of the output in India of minerals for which trustworthy returns of production are available, during the five years 1919–23 inclusive, was as follows:

	l.
Coal	9,252,649
Petroleum	7,036,298
Gold	2,094,323
Manganese ore	1,995,341
Salt	948,245
Lead and lead ore	881,710
Silver	642,450
Mica	633,331
Saltpetre	355,118
Tin and tin ore	214,500
Tungsten ore	135,845
Iron ore	114,956
Jadestone	114,329
Ruby, sapphire and spinel	60,660
Chromite	53,764
Monazite	29,294
Copper ore	29,053
Magnesite	16,334
Diamonds	7,262
Graphite	265
Total value	24,615,727

Of the countries in the British Empire, India stands second as regards coal output, being well ahead of the Union of South Africa, Canada, and Australia, although the output of rather more than twenty-one million tons in 1924 amounted to less than 8 per cent. of the output of Great Britain. Of the Indian output, more than 98 per cent. was from Gondwana coalfields, including 52 per cent. from the Jharia field and 28 from the Raniganj. The Bokaro field, with 4·7 per cent. of the output, is now ahead of the output of the Giridih and Singareni fields. It is expected that the Bokaro will before many years prove to be one of the great coalfields of India. Coal exports during the period ranged from a maximum of 1¼ million tons in 1920 to a minimum of 77,000 tons in 1922. In its coal export trade to ports in the Indian Ocean, India has to compete with Japan and South Africa, both of which countries are regarded as formidable rivals in this trade. The employment of by-product ovens in coke-making has of late been considerably extended, as also has the employment of electrical energy in mines for pumping, etc.

The large increase in annual value of the petroleum output from an average of 1,073,604*l.* during the period 1914–18, to an average of 7,036,298*l.* for the period under review, does not indicate a corresponding increase in the actual output, which averaged 282,594,121 gallons annually during the former period as compared with 299,453,675 during the latter period. The large increase in value referred to is attributed chiefly to the fact that the value of petroleum during the former period was much under-estimated, and partly to the high exchange value of the Indian currency in 1919 and 1920, during which years there was an increased output. The director of the Geological Survey thinks the chances are that the next five years will show a smaller increase of output than was shown by the last five years, and possibly even a decrease. India still contributes only a very small part of the world's supply of petroleum, the output for 1923 being only 0·83 per cent. of the world's marketed production.

The period was one of substantial progress for the iron and steel industry in India, which was in a declining condition at the outset of the quinquennium. In spite of this progress, however, a Tariff Board was appointed recently to inquire into the question of protection for the steel-making industry. As a result of its inquiry the Tariff Board concluded that, without some form of protection, the Indian steel industry would certainly not develop for many years, and might even cease to exist. Following the Board's recommendations, the Legislative Assembly quite recently (September 1925) agreed to a grant of a maximum of

---

[1] *Records of the Geological Survey of India.* Vol. 57: Quinquennial Review of the Mineral Production of India for the Years 1919 to 1923. By the Director and Senior Officers of the Geological Survey of India. Pp. viii+398+lxxi+5 plates. (Calcutta: Government of India Central Publication Branch, 1925.) 5 10 rupees; 9s. 9d.

60 lakhs of rupees to the steel industry up to March 1927, after which date, when the Protection Act expires, the question will be reconsidered.

India assumed leadership in the production of manganese ore so early as 1907, and, after a relapse in the years 1912–15, regained it during the War period, in spite of much competition from Brazil. The report states, however, that discoveries of new and valuable deposits of manganese ore seem to have ceased, and that the period under review has been marked by stability in this section of the mining industry, accompanied by gradual development of some deposits and exhaustion of others. The average annual output of manganese ore for the period was 624,635 tons, compared with 577,457 tons in 1914–18, and 712,797 tons in 1909–13.

The output of chromite (chromium ore), which had increased substantially during the War period, continued to increase during the period under review, the average annual output being 35,000 tons as compared with an average of 23,000 tons for the previous quinquennium. The increase was due chiefly to greater activity in the chrome mines of Baluchistan.

The output of tungsten ore in Burma, which had increased greatly during the War period, having reached 4542 tons in 1917, dwindled during the period under review to an output of 872 tons in 1923. The tin output, on the contrary, showed an increase to an average annual of 138 tons (metal) compared with an average of 116 tons for the preceding quinquennium.

The gold-mining industry of India suffered during the War period, during which the average production was a little less than 587,000 ounces annually. The decline in output has continued steadily through the period under review, during which the average was 459,875 ounces.

Further marked progress is reported in the output of the lead-silver-zinc mines at Bawdwin and Namtu in Burma. The output of lead extracted from the ore at these mines rose steadily from 19,000 tons in 1919 to 46,000 in 1923, while that of silver increased from more than two million ounces in 1919 to about five million ounces in 1923.

India is the leading producer of mica of good quality. We learn, moreover, from this report that the art of producing fine splittings of mica by hand is practised more efficiently in India than in other countries, so much so that during recent years India has imported mica for conversion into fine splittings for export. India also holds a monopoly in shellac production, which gives her power to control the production of micanite if necessary.

The average annual output of magnesite, chiefly from the deposits at Salem in Madras, increased by 77 per cent. in the period under review.

There was no progress in the jadeite industry during the period dealt with. The average annual exports amounted to 4628 cwt. as compared with 4651 cwt. during the previous quinquennium, but the value was much higher.

The output of monazite declined substantially during the period 1919–23, having fallen from 2000 tons in 1919 to only 125 tons in 1922.

The output of bauxite during the period continued low, averaging 5220 tons annually. The returns for 1924, however, show an increase to 23,228 tons of bauxite, from 6547 tons in 1923. By far the larger part of the 1924 production was from the Kaira district, in the Bombay Presidency.

Among new and interesting features in the mineral production of India, mention may be made of ilmenite, zircon, sillimanite, and kyanite. Ilmenite and zircon occur with monazite in the beach sands of Travancore, and are obtained as by-products in the magnetic concentration of the monazite. The outputs of ilmenite for 1922, 1923, and 1924 were 400, 700, and 641 tons respectively, while those of zircon were 160, 145, and 365 tons respectively.

Sillimanite has in recent years come into prominence as a refractory, and much interest has been taken in the deposit of the Khasi Hills, Assam, which was formerly thought to be one of corundum. Four outcrops of sillimanite have been found, but the extent of the deposit is not known. The quantity of boulders, etc., at the surface is stated to amount to about 3000 tons. No sillimanite appears in the production statistics of 1923 and 1924.

A discovery of kyanite was made in the Lopso Hill area, Kharsawan State, Singhbhum, in 1921. Analyses show the rock to consist of practically pure aluminium silicate, and experiments show that it is suitable for use as a refractory. Several hundred tons have been sent to England, and it is thought that a demand for it as a refractory may arise. An output of 224 tons of kyanite is reported in the production statistics of the Geological Survey for 1924.

T. C.

Obituary.

MR. J. H. MAIDEN, I.S.O., F.R.S.

ON November 16, at his residence, Turramurra, Sydney, the death occurred of Joseph Henry Maiden, who in 1924 retired from the position of Director of the Sydney Botanic Gardens and Officer-in-Charge of the Centennial Park. Mr. Maiden was born at St. John's Wood, London, on April 25, 1859, and received his early education at the City of London Middle Class School. He soon showed a taste for science, and for some time was assistant to the late Prof. F. Barff. He came to Australia in 1880, for health reasons, having provided himself with a return ticket, but the climate proved so beneficial that he decided to remain, and became associated with the formation of the Technological Museum, Sydney, of which he was Curator from 1881 until 1896, and he soon began to study the native plants. Some of his early botanical lessons were learnt from the late Rev. Dr. William Woolls, of whom he always retained the most affectionate memories. He was also a colleague in botanical work of the late Baron von Mueller in his latter days, another of the great pioneers of Australian botany. Mr. Maiden was Superintendent of Technical Education from 1894 until 1896; Consulting Botanist to the Departments of Agriculture and Forests from 1890; Director of the Botanic Gardens, Sydney; and Government Botanist from 1896 until his retirement in 1924.

The particular genus which Mr. Maiden studied most intensively was that almost exclusively Australian one —Eucalyptus—and he added very many new species to the list previously known, his field of investigation extending all over Australia. By his enthusiasm and energy he formed the present Herbarium at the Sydney Botanic Gardens, one of the finest in the southern hemisphere, and made many personal journeys in the various States for material to enrich his collections. He also, at considerable trouble, obtained type specimens which were collected in Australia in the early days, but had been housed in herbaria in other parts of the world, including some collected by Sir Joseph Banks in 1770.

Perhaps Mr. Maiden's greatest work in the field of botanical research is his "Critical Revision of the Genus Eucalyptus," of which sixty-four parts have already appeared and others are going through the press. Another valuable publication is the "Forest Flora of New South Wales," of which seventy-seven parts have been issued. Other publications included "Illustrated Flowering Plants and Ferns of New South Wales" and "Useful Native Plants of Australia." He made numerous contributions on various subjects to the *Agricultural Gazette of New South Wales*, and the service he has rendered in the interest of forestry in this State has been very great.

Mr. Maiden was honorary secretary of the Royal Society of New South Wales for twenty-two years, and president in 1896 and 1911; president of the New South Wales Horticultural Society for twenty years and of the Horticultural Association for eighteen years, as well as president of the Linnean Society of New South Wales and the Royal Australian Historical Society, in each case for two years. He was a man full of energy, and one of the most outstanding features of his activities was his industry. He never seemed to tire of writing up and placing on record any scientific facts which made for the advancement of knowledge, his contribution to the Royal Society of New South Wales being forty-five papers, the last having been presented in 1925, while his papers to the Linnean Society of New South Wales amounted to ninety-five. He entertained a very high regard for Sir Joseph Banks, whom he styled "The Father of Australia," and his biography of Sir Joseph, written chiefly for the purpose of raising funds for a memorial to that great botanist, is considered to be a classic. Mr. Maiden was one of the chief originators of the National Wattle Day Celebration in the Commonwealth, which has for its object the cultivation of an Australian national sentiment, while keeping in view that this country forms part of the British Empire.

In 1915 Mr. Maiden was awarded the Linnean Medal by the Linnean Society of London, this being the first occasion upon which this medal had been won by an Australian. He was elected a fellow of the Linnean Society in 1888, and in 1916 was honoured by having the Imperial Service Order conferred upon him, and also by being elected a fellow of the Royal Society. In 1921 he was offered the presidency of the Australasian Association for the Advancement of Science, but declined it for health reasons, and in 1922 was awarded the Mueller Medal by that body, of which he was honorary secretary for fourteen years; in 1924 he gained the Clarke Memorial Medal awarded by the Royal Society of New South Wales.

Mr. Maiden ranks among the half-dozen leading pioneering botanists who have contributed so much to our knowledge of the unique Australian flora, and for many years was regarded as the doyen of Australian botanists. He served as an inspiration to very many science students, probably more than ever will be known, and as some evidence of the affection and esteem in which he was held by his colleagues in science he was, in 1916, presented with his portrait in oils. In addition to the amount of scientific work which he carried out as the result of his own investigations, he was an outstanding benefactor to scientific progress generally, and being a born organiser added great strength to those societies which were reached by his influence. Truly it may be said of him that he left the world richer for his labours, and his life was filled with greatness, nobility and sincerity.

R. H. CAMBAGE.

WE regret to learn from the *Chemiker-Zeitung* of the death of Dr. Erich Krause, director of the laboratories of the Wood Carbonisation Co. of Constance. Krause was born at Weissenfels and educated at Leipzig and Vienna. At Vienna he became assistant to Prof. Skraup, in conjunction with whom much of his original work was published. The researches were partly in organic chemistry and partly in physical chemistry and were concerned mainly with the investigation of proteins. In 1911 he entered the service of the Holzverkohlungs-Industrie, when he devoted his energies to the perfection of analytical methods, his main results being published in the new edition of the well-known work of J. König, "Die Untersuchung landwirtschaftlich und gewerblich wichtiger Stoffe." In collaboration with his colleagues he worked out a process for obtaining methyl alcohol from natural gas. During the War, Krause devoted much time and attention to the problem of finding food-substitutes.

WE regret to announce the following deaths:

Dame Louisa Aldrich-Blake, D.B.E., Dean of the London (Royal Free Hospital) School of Medicine for Women, one of the first among medical women to practise general surgery, on December 28, aged sixty years.

Prof. Matthew Curry, formerly professor of engineering at King's College, London, on December 29, aged seventy-four years.

Dr. C. Gessard, of the Institut Pasteur, Paris, who isolated a pyocyanic bacillus from pus in 1882, and was also known for his work on oxydases and on bacteria generally.

Dr. J. G. M'Kendrick, F.R.S., emeritus professor of physiology in the University of Glasgow, on January 2, aged eighty-four years.

Prof. Alfred Perot, professor of physics in the École Polytechnique, Paris, and president of the Commission de Métrologie, on November 27, aged sixty-two years.

Sir R. Douglas Powell, Bart., K.C.V.O., physician in ordinary to the King, president of the Royal College of Physicians in 1905-10, and formerly president of the Royal Medical and Chirurgical, the Clinical and Medical Societies, on December 15, aged eighty-three years.

News and Views.

The list of New Year honours includes the following names of men of science and others associated with scientific work:—*Privy Councillor*: Lord Bledisloe, Parliamentary Secretary to the Ministry of Agriculture and Fisheries. *Baronets*: Mr. W. W. Butler, member of Council, University of Birmingham, and Sir Robert Jones, president of the Association of Surgeons of Great Britain. *Knight Commander of the Order of St. Michael and St. George* (*K.C.M.G.*): Prof. M. W. MacCallum, vice-chancellor of the University of Sydney. *Knights*: Prof. T. Hudson Beare, Regius professor of engineering, University of Edinburgh; Dr. R. A. Bolam, chairman of council, British Medical Association; Prof. J. B. Farmer, professor of botany, Imperial College of Science, South Kensington; Major A. McN. Cooper-Key, chief inspector of explosives, Home Office; and Mr. P. J. Hartog, vice-chancellor of the University of Dacca. *Companion of the Order of the Bath* (*C.B.*) (*Civil Division*): Mr. Arthur H. Smith, late Keeper of Greek and Roman Antiquities, British Museum. *Companion of the Order of the Indian Empire* (*C.I.E.*): Lieut.-Col. J. W. D. Megaw, director of the School of Tropical Medicine and Hygiene, Calcutta.

The New South Wales Government has announced its decision to close the State Observatory, which for many years has been under the control of Prof. W. E. Cooke. Owing to the growth of Sydney, the site of the Observatory has become quite unsatisfactory and its work has suffered in consequence. The necessity for removal to a distant suburb has repeatedly been urged upon successive State Governments; but the Labour Ministry's method of dealing with the problem has come as a distinct surprise. It is unlikely that this abrupt decision will mean withdrawal of governmental support of astronomical work in New South Wales, and it may serve a very useful purpose in focussing attention upon, and possibly leading to a settlement of, the question as to whether the individual States, or the Commonwealth, should take charge of such work. Some years ago the Commonwealth accepted sole responsibility for meteorological services, and the consequent co-ordination of effort has had highly satisfactory results. The establishment of the Commonwealth Solar Observatory at Mount Stromlo, Canberra, has already provided a precedent for the entry of the major Government into astronomical work, and there are many people who strongly favour its assumption of control over all the Observatories. The New South Wales decision will not take effect immediately, and in the meantime the whole situation, as it affects all the States, will be given most careful attention. Possibly this apparently hostile act on the part of a State government may prove, in the end, to be a blessing to astronomy in Australia.

It is only a year or two ago since G. F. and G. M. Dick in the United States described an intracutaneous immunity test for scarlet fever. They used a soluble toxin elaborated by a blood-destroying streptococcus microbe which was isolated from cases of scarlet fever, and they developed a new theory of this eruptive fever, namely, that it was really a localised disease of the throat caused by a specific streptococcus producing a toxin which, on absorption into the blood stream, gave rise to constitutional symptoms associated with a characteristic rash. Already the "Dick test" has been applied to enormous numbers of people especially in the United States, and it is now coming into prominence in the English medical Press. The *Lancet* of Dec. 26 contains three papers on the subject by Drs. Joe, of Edinburgh, Silcock, of Leicester, and O'Brien and Okell, of the Wellcome Research Laboratories. The paper of the last workers, entitled "Some Problems connected with the Dick Test," is particularly interesting, dealing as it does with the difficulties of the test and the real significance of negative and positive reactions as measures of the immunity in scarlet fever. It is known, broadly, that a negative response indicates a high degree of non-susceptibility to the disease, but Drs. O'Brien and Okell are not equally certain that a "positive" and particularly a "partial positive" reaction may not indicate some immunity. They also tentatively touch the question whether there may not be immunologically distinct types of the disease as occur in other well-known bacterial infections. Already there are some indications that the so-called streptococcus of scarlet fever may not be so specifically distinct as was believed a year back.

The rapid progress that is being made by telephony is proved by the statistics published in *Electrical Communication* last October by the International Standard Electric Corporation of New York. The problem of giving telephone service becomes more complicated every day. Every new subscriber makes the problem more difficult. In 1905 there were 300,000 telephone sets in operation in the New York metropolitan area. There are now 1,900,000, and it is estimated that by 1945 there will be at least four millions. The number of telephone stations at present is 130, 26 having been added during the last year. Some of these are enormous buildings serving 100,000 subscribers, and very costly to erect. The introduction of automatic switching adds considerably to the complexity of the problem. In the United States and Canada the number of telephones for each hundred inhabitants in 1924 was 13·7 and 11 respectively. In Europe, Denmark heads the list with 8·7, Sweden comes next with 6·7, and Norway third with 6·1. Germany has 3·8, Great Britain and North Ireland 2·5, and France 1·5. Curiously Great Britain, Germany, and Switzerland have almost exactly the same number of miles of telephone wire per inhabitant. The number of telegrams per inhabitant in all countries is only a small fraction of the number of telephone conversations. In the United States, Denmark, and Sweden the fraction was less than one-hundredth in 1923, and in Great Britain and France it was less than one-twentieth. Long-distance telephony is making very satisfactory progress in the United States. The Chicago-New York cable which was started in 1918 is practically completed. One of the most serious difficulties that had to be overcome was the effect produced by the changes of temperature occurring every twenty-four hours. This produced a thousand-fold difference in the amount of electrical energy received over the line from the same input. Automatic regulators are employed which vary the amplification introduced by the thermionic valve repeaters with the temperature of the cable conductors.

LIEUT.-COL. THE HON. CUTHBERT JAMES, president of the College of Pestology (Incorporated), sends us a long letter upon the steps which led to the conversion of the Incorporated Vermin Repression Society into the College, and the character and work of this institution, by way of comment upon the note which appeared in NATURE of December 12, p. 875, referring to a public appeal for twenty thousand pounds to establish a memorial to the late Prof. Maxwell Lefroy. We pointed out that the college had no connexion with the University of London and suggested that any memorial would be more appropriately associated with the Imperial College of Science, where Prof. Lefroy was professor of entomology, than with such a propagandist organisation as that of which Lieut.-Col. James is president. We do not doubt that, as he remarks, " so far as it lies in the power of the College to make it so, its affairs are arranged strictly according to Cocker," but the fact that the authorities of the Imperial College refused to take part in the meeting called by the College of Pestology to arrange for the proposed memorial is in itself sufficient to show their attitude towards the originators of the appeal and their intentions. Lieut.-Col. James informs us that his appeal committee would welcome the addition of Prof. Lefroy's scientific colleagues as members, and we are glad to make his invitation known to them and any others who may wish to support a movement to obtain by public subscription the sum of twenty thousand pounds for " a chair and centre of applied biology at the College of Pestology, Bedford Square."

A DISCUSSION was opened at the Institute of Actuaries at the end of October by Mr. F. A. A. Menzler with the hope of indicating extensions of the work of the actuarial profession. He suggested that the application of statistical methods in business may afford a useful opening for any one who has been trained to examine statistics scientifically. Unfortunately, he discounted his advocacy by saying that there is no need to know about correlation and by implying that, while the mathematics of correlation are frightening, the subject of sampling is easy. Modern work on small samples demands as much hard thinking on mathematical lines as correlation, and it seems strange that any one should approach the matter in Mr. Menzler's way before a body which has not only published a text-book dealing partly with correlation, but also examines to some extent on the subject. Apart, however, from the lack of accuracy in some of the views expressed about modern statistical methods, there is a strong case to be made for the use of all scientific machinery in practical work, and an inefficient or out-of-date instrument is as unwise in statistics as in anything else, as is indicated in the leading article of this issue. Nobody would employ any one but a trained chemist to do chemical analysis, but many concerns will hand over statistical analysis to any one who may be on the staff instead of employing someone really qualified to do the work. Our leading article (p. 37) indicates some aspects of the subject which merit the earnest consideration of scientific workers and business men.

AT the December meeting of the American Geographical Society, the following awards were announced:—The David Livingstone Centenary Medal for 1925 to Luis Riso Patrón, Director of the Oficina de Límites of Chile, for " scientific achievement in the field of geography of the southern hemisphere," in recognition of his contributions to Chilean cartography; Señor Patrón headed the first Chilean Commission to make a precise survey of the Cordillera of the Andes, and as director of the Oficina de Mensura de Tierras he was responsible for the great map of Chile on a scale of 1 : 500,000; the David Livingstone Centenary Medal for 1926 to Erich von Drygalski, of the University of Munich, for his work in the South Polar regions; Dr. von Drygalski carried out notable glaciological and other investigations in the Arctic as leader of the Greenland Expedition of the Berlin Geographical Society (1891–1893) and of the German Antarctic Expedition of 1900–1903. A Charles P. Daly Medal for 1925 to Brigadier-General David L. Brainard, in recognition of his achievements on the Lady Franklin Bay Expedition under Greely in 1881–1884; a Charles P. Daly Medal for 1925 to Captain Robert A. Bartlett, for his services to Arctic exploration; as commander of the *Roosevelt* (1905–1909) he took a leading part in Peary's expedition to the Pole; on the Canadian Arctic Expedition of 1913–1918 he commanded the *Karluk*, and in 1917, under his able seamanship, the Third Crocker Land Relief Expedition achieved success. A Cullum Geographical Medal for 1925 to Pedro C. Sanchez, Director of the Central Mexican Bureau of Geography and Climatology, in recognition of his contributions to Mexican cartography; he has been in charge of the geodetic service of Mexico since 1912; a Cullum Geographical Medal for 1925 to Harvey C. Hayes, research physicist of the United States Navy, for his invention of the sonic depth finder; a Cullum Geographical Medal for 1925 to Lucien Gallois, of the University of Paris, for his work in the advancement of geography; by notable contributions to the history of geography, and by his interpretation of the spirit of geographical science, he has extended his influence far beyond the bounds of France.

LECTURING on " Primitive Transport " at the Edinburgh and Lothians Branch of the Royal Anthropological Institute on December 15, Mr. K. G. Fenelon said that transport methods were developed in early times and among primitive peoples, and unusual modes of locomotion are frequently to be explained by the circumstances of the time or by the nature of the materials available. Thus the passenger- and goods-carrying wheel-barrow of the Chinese has its *raison d'être* in the narrow causeway raised in the middle of bad roads, canoes in the Arctic are naturally constructed of animal products, while in other parts vegetable materials are more usually employed. The beginnings of commercial intercourse between nations or peoples were generally by land. Primitive peoples living on islands, as those in the Pacific, may develop a considerable technique of canoe-building for purposes of war or trading. In such areas, however, the natural conditions have concentrated transport development along that line of progress to the exclusion of others. Man is undoubtedly the most primitive means of transport. The next stage of development is marked by the introduction of the pack animal. The earliest forms of vehicle would appear to be the slide-car or sledge. Though the origin of the cart is lost in antiquity, there seems to be little to object to in the usual theoretical explanation that it arose from the slide-car, the stages in transition being the use of log rollers, solid drum wheels, built-up drum wheels and the spoked wheel. The simplest types of canoes are improvised from solid tree-trunks. The next stage is the dug-out canoe, planks being often added to give a greater height above water level. Bark, wicker and skins are also utilised. The outrigger canoe may have been evolved from rafts raised on floats. The sail is widely distributed, though curiously enough it seems to have been little known among the natives of North and South America.

THE *Kew Bulletin* announces that Mr. C. C. Calder, Curator of the Herbarium of the Royal Botanic Garden, Calcutta, has been appointed Director of the Botanical Survey of India and Superintendent of the Royal Botanic Garden, Calcutta, and of Cinchona Cultivation in Bengal.

PROF. F. P. SLATER, formerly head of the Physical Laboratory in the Experimental Department of the Fine Cotton Spinners and Doublers Association, Ltd., and lately professor of textiles in the University of Manchester, has been appointed chief of the Experimental Department of the Association in succession to Dr. W. Laurence Balls.

THE Ministry of Agriculture and Fisheries has re-imposed, starting on January 1, the admission fee of one penny—on other than students' days—to the Royal Botanic Gardens, Kew, which was abolished in April 1924, and previously yielded a revenue of about 5000*l*. per annum. The present admission fee of 6d. on students' days (Tuesdays and Fridays) will continue to be charged.

DR. G. CLARIDGE DRUCE was elected a corresponding member of the Société Botanique de Genève at the recent jubilee celebrations. Dr. Druce has just completed his account of the botany of Huntingdonshire in the "Victoria History of the Counties of England," which treats of about 800 species; he has already completed accounts of the botany of the counties of Berks, Bucks, Oxford and Northampton for this work.

A CONFERENCE on "The Growing of Lucerne" will be held at the Rothamsted Experimental Station on Wednesday, January 27, at 11.30 A.M. The chair will be taken by the Right Hon. Lord Clinton, and the speakers will include Sir E. J. Russell, Prof. R. G. Stapledon, Mr. J. Mackintosh, Mr. A. Cunningham and Mr. H. G. Thornton. Those intending to be present should notify the Secretary, Rothamsted Experimental Station, Harpenden.

THE French Government has conferred upon Sir Robert Hadfield, Bart., the Cross of an Officer of the Legion of Honour, in recognition of his noteworthy contributions to our knowledge of metallurgy. Sir Robert was elected a corresponding member of the Paris Academy of Sciences in 1923, and recently presented a paper to the Congress of Industrial Chemistry organised in Paris by the French Society of Chemical Industry, in which he showed the great debt which metallurgy owes to French scientific workers.

THE Dyers' Research Medal for 1924–25, offered by the Society of Dyers and Colourists, has been awarded to Dr. F. M. Rowe for the paper entitled "The Identification of Insoluble Azo Colours on the Fibre and of Azo Pigments in Substance," which was published in the July 1924 issue of the Society's journal, and a Certificate awarded to the co-author, Miss Clara Levin. The Medal is offered each year by the Company for the best scientific research or technical investigation connected with the art of dyeing submitted to the Society for publication in its journal.

PROF. DAYTON C. MILLER, professor of physics in the Case School of Applied Science, Cleveland, Ohio, has been awarded the American Association Prize of 1000 dollars for his paper on "The Michelson-Morley Ether-Drift Experiment, its History and Significance," delivered at the recent Kansas City meeting of the Association. The Prize, which was founded by a member of the Association shortly before the Cincinnati meeting in 1923, is given annually for "some noteworthy contribution to scientific advancement presented at the meeting" of the Association.

THE Carnegie Trust of the United Kingdom has generously come to the assistance of the Geographical Association with a gift of 1000*l*. towards equipping the Library of the Association, especially in the matter of sets of foreign periodicals. The Carnegie Trust is specially interested in assisting isolated students and has organised the Central Library for Students, Galen Place, W.C.1, with this in view. The Library of the Geographical Association will henceforth be affiliated to that Library, and the Association hopes that its usefulness to teachers and students all over Great Britain may be thereby increased.

A MODERATELY strong earthquake was felt about 12.30 P.M. on December 23 in the island of Mull and the district around Oban. The shock lasted about five seconds and was accompanied by the usual rumbling noise. The earthquake seems to have originated in or near the same centre as the Oban earthquakes of November 28, 1880, and January 17, 1907, which disturbed areas of about 50,000 and 3100 square miles respectively, the former being felt over nearly all Scotland and in the north-eastern counties of Ireland If the tremor observed at Bothwell at about 12.35 P.M and in Glasgow should prove to be connected with it, the shock was probably rather stronger than that of 1907. So far as known, no damage was caused by the earthquake.

THE sixth International Ornithological Congress will be held at Copenhagen on May 24-29 under the presidency of Dr E Hartert, of the Zoological Museum, Tring The work of the Congress will be divided into five sections dealing respectively with. (1) Systematic ornithology, geographical distribution, palæontology; (2) anatomy, physiology, heredity and evolution, (3) biology, including ecology and bird migration, (4) oology, nidification, (5) bird protection and aviculture The executive committee of the Congress includes representatives of Denmark, France, Germany, Great Britain, Sweden and the United States; the British members are Messrs W. Sclater and H. F Witherby Communications for the Congress should reach the honorary secretary, Mr. P. Bovien, c/o Mr E Lehn Schioler, Uraniavej, 14-16, Copenhagen, Denmark, not later than May 16

ACCORDING to the Rome correspondent of the *Times*, the Italian cabinet has approved a bill creating an Italian Academy, the objects of which will be the "co-ordination and direction of Italian intellectual movements in the field of science, letters, and arts, the preservation in these activities of the national character according to the traditions of the race, and the encouragement of its expansion and influence abroad" The Academy will receive an annual subsidy from the State, and grants and pensions will be assigned to authors, artists, and scientific workers, inventions examined and schemes for intellectual advance instituted Membership will be limited to sixty, the first thirty being nominated by Royal decree, on the advice of the President of the Council, and the remainder during the next ten years from a list of names preferred by the existing Academicians Academicians will have the privileges of high State officials and will wear a special uniform

WE learn that the beam stations for short wave radio communication which Marconi's Wireless Telegraphy Co, Ltd, is erecting for the British Government and for the Governments of the Dominions and India, are making satisfactory progress It had been hoped that the Canadian and South African stations would be ready for working by the end of 1925, but their completion has been delayed by the illness of Senatore Marconi and Mr Franklin It is expected, however, that the beam services between Great Britain and Canada and South Africa will be ready for working in April next, and that the services with India and Australia will be in operation about the middle of August A beam station is being erected at Dorchester for communication with the United States and with South America. A corresponding station is being built in Brazil for the account of the consortium of the four wireless companies operating in South America The Company is also constructing stations connecting Portugal and her Colonies and linking up Portugal with the rest of the world. This programme of construction involves the expenditure of approximately 1,000,000*l.* sterling

IN referring to the report of the British Photographic Research Association (December 26, 1925, p 944), we perhaps did not make it sufficiently clear that while the members of the staff of the Association took a very active part in the matter of the standardisation of plate-testing methods, the proposals that were placed before the sixth International Congress of Photography were drawn up by a committee appointed by the Scientific and Technical Group of the Royal Photographic Society.

WE have received the annual report and statement of accounts of Livingstone College for 1924-25 The College does a valuable work in imparting to those entering the mission field the elements of a medical training. Owing to a decrease in fees and extraordinary expenditure on making up roads adjoining the College there is a deficit on the year's working of 1340*l.* Subscriptions are appealed for, either for general purposes or to provide a memorial to the late Dr. Harford, the founder and first principal.

IN the notice of the Ray Society volume, "The British Hydracarina," by C. D. Soar and W. Williamson, in NATURE of December 26, 1925, p. 932, the bibliographic details might be taken to imply that this book was published by the British Museum (Natural History). We are asked to point out that this is not the case, and that the Ray Society has no official connexion with the British Museum apart from the fact that permission has been given for the Museum to be used as the official address of the Secretary of the Society Messrs Dulau and Co, Ltd, 34-36 Margaret Street, London, W 1, are the agents for the sale of the Society's publications to non-members and to the trade

APPLICATIONS are invited for the following appointments, on or before the dates mentioned · A professor of mycology at the Imperial College of Tropical Agriculture, Trinidad—A Aspinall, Imperial College of Tropical Agriculture, 14 Trinity Square, E C 3 (before end of January). A head of the Electrical Engineering department (*not engineering* as advertised in NATURE of January 2) of the L C C Hackney Institute—Education Officer (T. (1) (a)), County Hall, Westminster Bridge, S E.1 (January 18). A borough analyst and Corporation chemist for the County Borough of Salford—Medical Officer of Health, 143 Regent Road, Salford (January 20) A demonstrator in inorganic and physical chemistry at King's College, London—The Secretary (January 20) A Secretary to the Queen's University, Belfast—The Vice-Chancellor (January 30) A senior lecturer (male) in zoology in the University of the Witwatersrand, Johannesburg—The Secretary, Office of the High Commissioner for the

Union of South Africa, Trafalgar Square, W.C.2 (February 15). A dairy bacteriologist at the Harper Adams Agricultural College, Newport, Salop—The Principal. A junior professional assistant in the Meteorological Office—The Secretary. (S.2), Air Ministry, Adastral House, W.C.2. A research assistant in the physiology department of the Middlesex Hospital Medical School—The School Secretary, Middlesex Hospital Medical School, London, W.1. A temporary lecturer in mathematics at the University College of Swansea—The Registrar, University College of Swansea, Singleton Park, Swansea.

Our Astronomical Column.

COMET ENSOR.—A little more information has come to hand about this comet, which raises hopes that it may be an object of considerable interest next February and March. A telegram from the Cape Observatory was circulated by the I.A.U. Bureau on Dec. 18; it gave the position on Dec. 14 at $18^h\ 30^m$ U.T. as R.A. $3^h\ 38^m$, S. Decl. 61° 12′; daily motion minus 12 minutes of time, south 24′. A further telegram from S. Africa appeared in the *Times* of Dec. 19, stating that an orbit had been deduced which indicated Feb 12 as the date of perihelion, and some thirty million miles as the perihelion distance. These facts, with the above position and motion, have enabled Dr. A. C. D. Crommelin to deduce the following rough orbit:

$$T = 1926,\ \text{Feb. } 12{\cdot}5\ \text{(assumed).}$$
$$\omega = 5^\circ\ 16'$$
$$\Omega = 284\ \ 17$$
$$i = 123\ \ 13$$
$$\log q = 9{\cdot}4072$$

An ephemeris from this orbit shows that the comet may be expected to be visible in England about Feb 16, when it will be a morning star 1° east of the sun, and 4° north of it; it may then be visible in the twilight and have a considerable tail (it had one 15′ long at discovery). It continues its northward course, and by March 4 will be 35° north of the sun; it will rise 4½ hours before sunrise, and will thus be visible on a dark sky; it will afterwards become circumpolar, but will fade rapidly. This forecast should only be taken as giving a general idea of the course of the comet, the data being rough. But it may be expected to be the brightest comet since Mellish's of 1917.

The following elements have been telegraphed to the I.A.U. Bureau, Copenhagen; they were computed by Mr. H. E. Wood, of the Union Observatory, Johannesburg, from observations made there on Dec. 14 to 16 (about):

$$T = 1926,\ \text{Feb. } 12{\cdot}41\ \text{U.T.}$$
$$\omega = 353^\circ\ 44'$$
$$\Omega = 282\ \ 17$$
$$i = 122\ \ 52$$
$$\log q = 9{\cdot}5250$$

EPHEMERIS FOR 0^h

	R.A.	Decl.	log *r*.	log Δ.

NAKED-EYE SUNSPOTS.—On the few days during the past three weeks when observations of the sun were possible, a number of sunspots were visible. Two of these were so large that they were obvious naked-eye objects. The first of the two groups, consisting of a pair of large spots, was south of the sun's equator, and crossed the central meridian on Christmas day. The other group, made up largely of one great spot, was in north latitude 23° and was on the meridian three days later. It is the largest group of spots seen as yet this cycle, and is comparable with the largest groups of the preceding cycle, such as the great spot of August 1917 or the long stream of March 1920.

Of the three large spots noted in these columns in the issue of December 9, the third group (Nov. 18-30, latitude 17° N.) lasted long enough to cross the disc again. The leader spot of the stream was alone represented, however, but though the train had died out, its position was marked by an extensive region of bright faculæ clearly seen near the east and west limbs of the sun.

The following table continues the information of naked-eye sunspots given in two previous numbers:

Date on Disc (1925–26).	Central Meridian Passage.	Latitude.	Maximum Area.
Dec. 19–31	Dec 25·4	20° S.	1/550
Dec. 22–Jan. 3	Dec 28·3	23° N.	1/400

(Areas express the proportion covered of the sun's hemisphere.)

On December 27 and 28, two moderate magnetic disturbances were registered at Greenwich, the time corresponding roughly to that of the transit of the large northern spot. The movements shown by the magnets were, however, much inferior to those of a "magnetic storm." There have been no other recent magnetic disturbances of any consequence.

The year 1925 has shown a pronounced increase in the number and size of sunspots, especially during the latter half of the year; but the average latitude (about 20°) in which the spots have appeared indicates, from their corresponding latitude and frequency in previous cycles, that their maximum occurrence will be nearly two years hence.

THE DECEMBER METEORS.—Mr. W. F. Denning writes: "This shower was unusually strong this year on several nights, especially on December 12 and 13, and the time of greatest abundance appears to have been observed on December 12 at about 20^h new G.M.T. Mr R. M. Dole of Lansing, Michigan (Lat. 43½° N., Long. 85° W.), says: 'The Geminids were magnificent this year. The rate on December 10 was 30-40 per hour from a point about 2° W. of Castor. On December 12 the radiant was between α and β Geminorum 1/5 the distance from α to β.' He watched the shower between $7^h\ 45^m$ P.M. on the latter night and $2^h\ 3^m$ A.M. (local time) December 13. The horary rate at about 10 P.M. was 60, and this went on increasing so that at 2 A.M. the rate was more than 240 per hour. They were short, swift, red, very few left trails. A great number were about 6-7 magnitude. At about 1 50 A.M. several bright ones were seen, mostly dark red. It is possible that the maximum may have been after 2 A.M. The display seems to have been nearly equal to that witnessed on December 13, 1920, in the early morning, by two ladies at Bournemouth, when at the lowest estimate 5 per minute were counted, or 150 in half an hour's record, though the sky was partially cloudy.

"The meteors were also seen at their recent return by Mr. A. King, in Lincolnshire, who obtained a very successful series of observations on the nights December 10-14. He did not witness the same abundance as that reported from the United States, but conditions were not so favourable. On the early evening of December 13, meteors were casually observed to be surprisingly numerous by Mr J. Johnson and some friends from the Devonshire moors.

"The writer pointed out the probability of a rich return of these meteors on December 12, 20^h (new G.M.T.), in *Monthly Notices, Roy. Ast. Soc.*, vol. 84, p. 178. Mr. Dole's observation has proved that it occurred at the time and in the strength expected."

Research Items.

A PORTRAIT-STATUE FROM THE CONGO.—In *Man* for December, Mr. T. A. Joyce figures and describes an example of the royal portrait-statues of the Bushongo. Four of these statues were brought back from the Congo by Mr. Torday in 1909, of which three are now in the British Museum and one in the Musée du Congo Belge, Tervueren. This present example, the fifth known, which has recently been acquired by the Musée du Congo Belge, represents Mikope Mbula, 110th paramount chief of the Bushongo. Native report states that these statues of chiefs were carved only when an artist of sufficient calibre was discovered. The statue of Mikope Mbula conforms to the traditional pattern. It is of hard reddish wood and is some 62·8 cm. in height. The chief sits in the conventional cross-legged pose, his left hand holding a knife, his right on his knee. His ornaments and dress—a belt ornamented with cowries and a belt supporting a sitting cloth and armlets—are indicated by carving. An engraved brass ring is around his neck. The five statues are evidently the work of three different artists, of whom the sculptor of the present figure is inferior in expression of character, although in two points at least he is more correct—the proportion of the lower limbs and the details of the hands. The distinguishing emblem of this chief is a human figure sculptured on the plinth in front of him which may represent his slave-wife and refer to the fact that in his reign, marriage with a slave—previously forbidden—became a legalised practice.

SUMERIA AND INDIA.—In the October issue of the *Journal of the Royal Asiatic Society*, Mr. Mackay returns to the question of early relations between Mesopotamia and India which was raised by Sir John Marshall's description and illustrations of seals and other objects from the Indus Valley in the *London Illustrated News* of September 27, 1924. The seal, showing a figure of a bull standing over a heap of grain and three signs, one of them a fish, was found in 1923, in a chamber nearly two metres below the surface on the north-east side of the ziggurat of the Temple of Ilbaba at Kish, but is undoubtedly of earlier (Sumerian) date. Its resemblance to the seal found at Harappa is unquestionable. Further evidence of contact is seen in a number of beads, necklaces of carnelian and lapis lazuli, found in the last two seasons in graves at Kish, which are provisionally dated at 3000 B.C. The lapis lazuli might have come from Persia, but in view of the fact that India from time immemorial has been the home of carnelian working, the beads were submitted to Sir John Marshall, and pronounced by him to be similar to beads found in great quantities in India, dating from early to recent times. The technique of the Kish beads seems to be identical with that of the Indian beads. Every consideration points to India having been their place of origin or else a country with trade relations with both India and Mesopotamia. The lapis lazuli beads do not show the same finish in workmanship, and were therefore probably made by a different people.

SEA TROUT.—An addition to the steadily accumulated mass of valuable data, due to the work of the scientific staff of the Fishery Board for Scotland, with regard to the salmon and sea trout is given us by Mr. G. H. Nall in a "Report on a Collection of Sea Trout Scales from the River Hope and Loch Hope in Sutherland" (Fishery Board for Scotland, Salmon Fish., 1925, No. 1, Edinburgh and London, H.M.S.O., 3s. net). The material examined was collected during January and March, and July and August. Whilst the bulk of the scales were of normal type, there were some on which a period of rapid growth in winter was followed by a winter zone and a weak summer growth in the following year; on others there was little differentiation between river and sea life. Erosion was well marked in autumn and winter on the scales of maturing fish and kelts, but, in some cases, the erosion which was slight and regular round the periphery of the scales suggests the possibility of spawning marks being undetected occasionally. The greatest number of smolts, 60 per cent., migrated to the sea after three years' river life, 10 per cent. after two years, 26 per cent. after four years, and 4 per cent. after five years. For the Forth, Menzies found 68 per cent. migrating after two years, 31 per cent. after three years, and an odd fish going down after four years. As is pointed out by Mr. Nall, this illustrates the rule that the farther north a district lies the longer is the parr life. The data show a tendency for the younger smolts to mature later than do the older smolts. The period between the smolt migration and the first spawning varies from one to four years; the greatest numbers spawn in the second winter after migration as smolts, and those which do not spawn until the third winter are more numerous than those which spawn as finnock; after first maturity, the majority of the fish become annual spawners. Information respecting three out of seven recaptured marked trout was sent without an accompanying sample of scales. This is unfortunate and suggests the desirability of giving more publicity to the experiments. It is also desirable that some records of temperature be made during winter feeding to check the statement that abundance of food, not high temperature, is the dominant factor in producing wide rings on the scales of the Salmonidæ.

ENZYME IN PLANT GUMS.—Oxidase and diastase activity have been found in plant gums by Gilbert J. Fowler and M. A. Malankdar (*Journal of the Imperial Institute of Science*, Bangalore, Vol. 8 A, Part 12), these enzyme activities being much more marked in two gum-oleo-resins, myrrh gum and the gum of *Boswellia serrata*, than in gum-arabic. In the case of the Boswellia and myrrh gums, there is evidence that the oxidase may consist of the usual peroxidase-oxygenase system, and an alcohol soluble catechol compound may form part of this system. Analyses for manganese do not suggest that the traces of this element present can be correlated with the oxidase activity. The diastatic enzymes saccharify starch solutions, but are without action on unchanged starch or gum and have no dissolving action on hemi-celluloses. There is a note of some interesting experiments suggesting enzymic conversion of tannins into non-tannins by extracts of these gums.

THE ANDAMAN SEA BASIN.—Major R. B. Seymour Sewell has commenced a systematic study of the Indian Seas, and in a first paper (*Mem. Asiatic Soc. Bengal*, vol. 9, No. 1, 1925) he deals with the geotectonics of the Andaman Sea. The Andaman-Nicobar ridge connects the Arakan Yoma with the main ranges of Sumatra. It probably began to rise from the sea-floor in early Tertiary times as part of the outer arc of the great Alpine-Himalayan system. Simultaneously a shallow-water basin formed on the east, into which poured the great alluvium-charged rivers of Burma, and from which the waters escaped into the Bay of Bengal through channels between the Islands. At a much later date the Straits of Malacca were formed and permitted the entry of the Pacific shallow-water fauna into the Andaman Sea, where already an Indian Ocean fauna was flourishing. The same sequence of structural elements—upfolds, depressions and volcanic belt—can be traced across Burma, from the Bay of Bengal to the Mergui Archipelago, and from the Indian Ocean across Sumatra to the Malayan ridge. The greater part of the Andaman Sea is a large basin, but on the west it is complicated by the volcanic belt of Barran Island and Narkondam. Farther south, olivine-basalt has been dredged from a depth of 1240 fathoms, 35 miles east of the Central Nicobars. The distribution of coral-rock throws new light on the recent development of the Andaman anticline. Raised coral-beaches along the eastern coasts of the Islands indicate uplift, while a barrier reef, much interrupted, occurs on the west and points to subsidence on that side. Many other topics of geological and oceanographic interest are discussed; and all the available data of a fascinating and little known region are brought to bear on the problem of its origin and evolution.

CRETACEOUS GASTROPODA FROM PORTUGUESE EAST AFRICA.—Mr. L. R Cox has described a series of Gastropoda from Catuane and Incomanini in Portuguese East Africa (*Ann. Transvaal Mus*, 11, Pt 3) The deposits at the former locality are considered to be Upper Albian, while those of the latter probably belong to the Upper Mæstrichtian. The Catuane fauna is represented by nine species, three being described as new, while in point of numbers an indeterminate Chenopus is the most abundant form present. Of the sixteen species in the Incomanini fauna, not one has been identified with any previously known form, but they appear to indicate shallow-water and possibly estuarine conditions at the time of the deposition of the beds The two plates on which these fossils are represented are very unsatisfactory.

NEW MAGNETIC ALLOYS.—In the September issue of the *Journal de Physique*, M. H. Tscherning gives the results of his comparison of the magnetic properties of the new alloys "permax," manufactured by the Imphy Steel Works, and "permalloy," manufactured by the Western Electric Co. Both specimens were in strip form and were coiled spirally to make rings on which were wound the magnetising and induction coils. The induction coils were connected to a Grassot fluxmeter, the readings of which were taken for each change of current in the magnetising circuit. For a maximum field of 1 gauss, permax has an induction of 3350 gauss, a residual of 2760 gauss, and a coercive force of 0·45 gauss. Under the same conditions, for permalloy the figures are 7500, 4900, and 0·075 respectively. With the maximum field raised to 200 gauss, permax has an induction of 10,800 gauss, residual about 5000 gauss, and a coercive force only 0·48 gauss, while for permalloy and for electrolytic iron the figures are of the order of 19,000, 10,000, and 1 respectively. Permax is therefore inferior to permalloy in permeability but has a smaller hysteresis loss in strong fields and seems less liable to change its magnetic properties under rough treatment.

THE NUCLEUS OF RADIOACTIVE ATOMS—In a paper in the *Comptes rendus Acad. Sci*, Paris, of November 20, M. J. Thibaud assumes that a radioactive nucleus consists of a very dense central portion with a total positive charge Ne, that the force around it is central and given by the formula

$$F = Ne^2(1 - b^{a-2}/r^{a-2})/r^2,$$

and that certain positive elements of the nucleus move as satellites round this central portion in the narrow region where the force upon them is attractive. It can be shown that the only periodic orbits possible are circles and that the motions in them are unstable, which would account for the disintegration of these atoms. It is assumed that these orbits are quantised, like Bohr's electron orbits in the external portion of the atom. The γ-rays emitted by these elements apparently obey quantum laws, and the author finds in the case of mesothorium 2, by assuming $a = 3$, $N = 100$, $b = 3{\cdot}29 \times 10^{-12}$ cm. and that the emitting particle is a proton, that the energy differences $W_n - W_1$ as observed and as calculated are almost identical, n the quantum number having the different values 2, 3, 4 . . . 8 N and b agree with values obtained for the charge and diameter of a heavy nucleus by studying the deviations of colliding α-particles. The agreement is not so good when a is assumed to be 4 with a revolving α-particle.

THE AMMONIUM RADICAL.—Direct experimental evidence for the tetrahedral distribution of the hydrogen atoms of the ammonium radical about the nitrogen atom in simple ammonium compounds is given by W. H. Mills and E. H. Warren in the *Journal of the Chemical Society* for November. Spiroammonium salts were investigated and, by a simple diagram, it is shown that resolution is possible if the ion has the tetrahedral configuration Fractional crystallisation of the bromocamphorsulphonates yielded *d*-spiroammonium bromide, molecular rotation $[M]_{5461}$ of $+50{\cdot}5°$ and the corresponding *l*-salt $[M]_{5461}$ of $-50{\cdot}8°$.

PHOTOCHEMICAL DECOMPOSITION OF SILVER CHLORIDE.—The microbalance has been employed by E J. Hartung to investigate the photochemical decomposition of silver chloride. The work is described in the *Journal of the Chemical Society* of November; thin films of chloride on silica sheets were sealed in tubes with different chlorine absorbents. After insolation for definite periods, the tubes were opened, air, nitrogen, or hydrogen admitted, and the films weighed The decomposition into silver and chlorine has a maximum value of 91·1 per cent, 89·8 per cent., and 94·8 per cent, in air, nitrogen and hydrogen respectively. In addition, experiments on the rate of chlorination of silver and previously insolated silver chloride are described, and these show that a maximum rate exists for certain concentrations of chlorine in air. No evidence of the existence of a subchloride was obtained.

ORIENTATION OF CRYSTALS IN METALS.—Two papers in the *Memoirs of the College of Science of the Kyoto Imperial University*, Ser. A, Vol. 8, No. 5, Aug. 1925, deal with the orientation of the crystals in cold-worked metals of the face-centred cubic type The X-ray patterns obtained from platinum plates which have been cold-rolled from a thickness of 0·5 mm. to 0 03 mm. suggest that the majority of the crystals are so arranged that a dodecahedral face lies parallel to the rolled surface, the direction of rolling being perpendicular to a trigonal axis lying in this face. This ideal arrangement does not exactly hold for all the crystals, the dodecahedral planes of some being rotated slightly around the direction of rolling. In the case of gold leaf, the surface of the leaf is a cube face. A second investigation of the orientation of the crystals in cold-drawn aluminium wire suggests that a trigonal axis lies nearly parallel to the axis of the wire, the orientation being otherwise somewhat at random. The deviation of the trigonal axis from that of the wire is most generally about 7°. The exact amount of reduction in drawing is not given. An examination of a cold-drawn copper wire shows that the orientation of the crystals is identical with that in aluminium.

Some Diseases of Cotton as seen in the Plantations.[1]

IN order to facilitate research work being carried out in the University of Manchester, for the Empire Cotton Growing Corporation, a visit was paid to some of the cotton states of America in the summer of 1924. The diseases of cotton described were observed in the plantations of North and South Carolina. In that season, according to recently published estimates by the U.S. Department of Agriculture, fungal and bacterial diseases of cotton reduced the crop in the U.S.A. by 1,900,000 bales. The extent of these losses in what was a relatively favourable season for cotton-growing indicates the importance of these diseases.

In the United States some diseases are more important than others, but, at the present time, all of them may be important to Great Britain in view of the considerable extension of cotton-growing in progress in various parts of the British Empire. In some of these countries a new crop plant is being introduced; we have little knowledge how it will react to its new environment and we do not know what diseases will appear. It is certain, however, that some diseases will occur, and it is well known that a disease which is relatively harmless in one country may become destructive in another. This may be illustrated by some of the diseases seen in the United States. *Bacterium malvacearum* causes the angular leaf spot and a boll disease on Upland varieties of cotton (*Gossypium hirsutum*), the leaves and bolls usually being the only parts of the plant affected. The Sea Island and Egyptian varieties of cotton (*G. barbadense* and *G. peruvianum*) are much more susceptible to the attacks of the organism, which also affects the leaf-stalks and branches, causing the "black arm" form of the disease. This "black arm" disease is already causing serious concern in the Sudan on Egyptian cotton, although in Egypt, presumably on account of the different climatic conditions, it is not troublesome. It is now known that infection may be carried on the seed, and seed-disinfection has proved successful in preventing the disease in the United States.

Again, in the U.S.A. several root-diseases of cotton occur. Of these the Texas root-rot (Ozonium) and the wilt disease caused by *Fusarium vasinfectum* are of most importance. In the latter case the disease was studied in South Carolina on badly infected soils. The fungus present in the soil passes into the conducting tissues of the plant and, excreting poisonous substances, leads to dwarfing, wilting and killing of the whole plant. In the Sudan a root-disease (the Tokar root-rot), undoubtedly different from the Fusarium wilts or Texas root-rot, but capable of stunting and killing the plant by progressive infection, is also causing trouble. Work at present in progress on this disease should ultimately determine its cause and probably provide for its control.

Diseases of the immature or opened bolls are commonly caused in the U.S.A. by *Glomerella gossypii* (anthracnose disease), Fusarium, Diplodia, and by *Bacterium malvacearum*. The cotton lint is destroyed, weakened or discoloured by such organisms. Similar boll diseases occur wherever cotton is grown, and recent studies by Mr. R. W. Marsh on discoloured cotton from Nyasaland have shown that the yellow discoloration is due to a species of Nematospora, a fungus. In the West Indies this fungus has been shown by Nowell to be inoculated into the bolls by cotton stainer bugs, which puncture the bolls as they feed. Stainer bugs were observed feeding on cotton bolls in South Carolina, but up to the present the Nematospora fungus is not known to cause disease of cotton in the U.S.A.

Other diseases of cotton studied were those caused by species of Alternaria and *Ascochyta gossypii*. These have not hitherto been of serious consequence in the United States, but the latter is now spreading and both diseases may prove much more harmful in other countries.

Of the diseases to which reference has been made, several have as yet been imperfectly studied, and only by extended work on such diseases and on the organisms responsible for them will it be possible for the growers and plant pathologists in cotton countries to guard against outbreaks of disease and to devise satisfactory means of control when such outbreaks occur.

---

[1] Substance of paper read before the Manchester Literary and Philosophical Society by Dr. Wilfrid Robinson on December 8.

Causes of Volcanic Activity.

ON the occasion of the centenary of the Franklin Institute in 1924, Dr. A. L. Day delivered an address on volcanic activity, which appears in the journal of the Institute for August 1925. It is well known that the crater of Mauna Loa is 10,000 feet higher than the lava lake of Kilauea. Since more lava emerges from the higher vent than the lower, and eruptions rarely occur simultaneously, it is clear that the two vents cannot be connected with a continuous liquid interior. The changes of level of the lava of Kilauea would show periodic tidal effects if there were a molten cauldron underneath, but they fail to do so. Moreover, the lava lake was recently drained to a depth of 1500 feet, and a solid relatively cold bottom was exposed. A number of channels leading in from below were detected on the side walls.

Another firmly established conclusion is that the varying temperatures and fluidity of the lava are due to irregular uprisings of gases. These have evidently come from isolated chambers in which crystallisation is approaching completion, but at different stages from place to place. The gases pass up through various channels into the central basin, where they meet and react, and so produce the heat necessary to maintain the superficial vulcanism. The gases actually collected from the lava include hydrogen, chlorine, and sulphur, which, in association with others, make an unstable mixture that could not have come from any single source, since it is in a state of active exothermic reaction.

Modern volcanoes thus appear to be controlled by the liberation of gases from a crystallising mass below, and are very different phenomena from the fissure eruptions that gave rise to the great basalt plateaux of the Deccan and the Brito-Arctic region. The conclusion is amply confirmed by the study of the recent explosions of Lassen Peak, which were essentially due to the release of steam from a closed chamber of crystallising magma beneath the crater. Practically no chemically active gases were discharged, and consequently the temperature remained much lower than at Kilauea, and no lava was emitted.

No other North American volcano, and few in the whole world, have been investigated so thoroughly as Lassen Peak, and the magnificent memoir by Dr. A. L. Day and Dr. E. T. Allen (Carnegie Inst. of Washington, Pub. No. 360, 1925) dealing exhaustively with its activity in 1914–17 will take a high place in the literature of vulcanism. Lassen Peak began its life as a volcanic centre in early Neocene times, and has continued with diminishing violence down to the present day. It is now an old and dying volcano, for the explosive eruptions which began in 1914 followed a period of apparent extinction which had lasted at least two centuries. Only once during its four years of activity were red-hot ejecta witnessed, and it seems to be completely established that high temperatures, such as are attained at Kilauea or Vesuvius, played no part in the eruptions. The first explosions broke through the snow-filled crater basin, and open cracks developed, down which the melted snow disappeared. A year later a lid or plug of dacitic andesite was forced up the vent to the level of the old crater-rim, and just failed to rise sufficiently to expose the underlying volcanic hearth. A plane of weakness was formed, however, on the north-east side of the cone, and through this two devastating horizontal blasts forced a passage. The adjacent valleys were stripped of all vegetation for four miles, but no fires were started save momentarily where a few dead leaves were ignited. Trees were merely scorched. Solid ejectamenta embedded themselves in the snow without melting any appreciable quantity. The great floods that followed a day or two later were most probably caused by the condensation of superheated steam from the volcanic cloud.

The outburst seems to have been assisted by an earthquake that weakened the structure of the volcano, and also by the flowing of water from melted snow down the first-formed cracks. But though this water must have participated in the tremendous steam-explosions that followed, it can scarcely have been an essential contributory cause, for the violence of the eruptions increased long after the snow had gone, and quantitatively it was inadequate to account for the enormous volumes of steam that escaped during the 300 or more explosions that afterwards occurred. Another source for the steam must therefore be postulated. The authors suggest that the gases responsible for the explosions were for the most part in solution in the crystallising magma beneath the crater, water being by far the most abundant ingredient of these volatile constituents.

It is now well known that a silicate magma can hold a considerable quantity of water in solution under appropriate conditions. G. W. Morey has pointed out (*Journ. Washington Acad. Sci.*, vol. 12, p. 219, 1922) that as crystallisation proceeds with falling temperature, the pressure of the volatile constituents increases at a rapid rate. This deduction from laboratory experience and thermodynamical reasoning goes far towards elucidating, not perhaps the entire problem of vulcanism as Dr. Day claims, but certainly most of the superficial phenomena of present-day volcanoes. The discharge of water during crystallisation must develop immense pressures when it takes place in a closed cauldron. The pressure may find relief in a single tremendous explosion, as in the case of Bandai San; or intermittently, as at Mt. Pelée or Lassen Peak, according to the rate of release of the water, and the roof conditions permitting or resisting its active escape. That the water-content of magmas before crystallisation is greater than that of crystallised rock is proved by the high percentage of water which is retained by obsidians and pitchstones.

The concluding sentences of Dr. Day's address summarise a long and consistently sustained argument: "Through all of these studies our conclusion seems to stand fast wherever it is applied, namely, that the outstanding factor in determining the character of modern vulcanism is the gas content of the crystallising magma. If this be mainly of steam released in a closed chamber, as at Lassen Peak, then only steam explosions are to be expected as the surface manifestation of the crystallisation of the magma below; if to the steam are added such chemically active gases as chlorine, sulphur, hydrogen and the hydrocarbons, then chemical reaction between these will be a sufficient cause of higher temperatures, and lava flows of the character well known at Vesuvius, Stromboli or Kilauea."

ARTHUR HOLMES.

Diseases of the Hop.

A NUMBER of interesting communications have recently appeared dealing with diseases of the hop. In particular a paper by E. S. Salmon and W. M. Ware (*Annals of Applied Biology*, 1925, 12, 121) discusses in detail a downy mildew which was first found in Europe in 1920 at the experimental hop gardens of Wye College. Since that year the intensity of the disease has been increasing rapidly, and it may become a serious factor in hop production in the future.

Previous to 1920 the disease was observed in Japan in 1905 (*Pseudoperonospora Humuli* (Miyabe and Takah.) Wils.) and in the United States in 1909, and there appears to be little doubt that the three diseases are identical. In 1923 the opinion was expressed that the fungus causing the disease had been imported into Great Britain from one of the countries mentioned, but subsequent work has led to the conclusion that it is indigenous. The downy mildew which is common to the nettle, *Peronospora Urticæ* (Lib.) de Bary, has been found to differ only as regards the size of the oospore from that occurring on the hop, and cross-inoculation experiments have led to the suggestion that the fungus may be transferred from one to the other. This is supported by the fact that infected nettles have often been found in close proximity to infected hops. Assuming then that the fungus from the nettle has found a new host, it would seem that the chance of infection becomes greater in a wet than in a dry season. This might account for the great increase in infection during the particularly wet season of 1924. On the other hand, a process of evolution may be taking place in which the hop is being infected by new forms of the downy mildew of the nettle, and in this case the prospect is rather more serious. Consequently the results of investigations during the 1925 season will be awaited with great interest.

It may also be mentioned that a similar disease has recently been noted for the first time in Germany, and as the nettle mildew is known to occur in the hop-growing districts of that country, some light may be shed on the problem from this quarter.

The disease is characterised by the appearance on the hop leaf of reddish-brown angular spots. Under the microscope these can be seen to consist of hair-like growths, which differ from ordinary hop mildew in that they are branched instead of unbranched. The branches bear conidia which drop off and spread the disease by germination in the presence of water. The hop cones may also be attacked, in which case the whole cone may turn brown and wither.

These symptoms must not be confused with those arising as a result of the "browning of cones" disease which in recent years has attacked hops on the Continent. This disease is also characterised by a shrunk epidermis which contains a reddish-brown substance, and has been ascribed by Wagner (*Tageszeit. Brau.*, 1924) to the exceptionally unfavourable weather conditions of 1924, rather than to a particular organism. P. Lindemanns (*Pet. Jour. du Brass.*, 1925, 33, 189) has stated that the disease was due to lack of nourishment of the cones. This was a result of the insufficient supply of sap, the transpiration being checked by the excessive humidity of the atmosphere. Thus, when the rows of hops had been planted in the direction of the prevailing winds, the disease was less marked than in the case of plants from damp and low-lying parts. J. G.

University and Educational Intelligence.

CAMBRIDGE.—Mr R. E. Priestley has been appointed Assistant Registrary with the duties of Secretary to the Boards of Examinations and Research Studies. Mr. Priestley was a member of two Antarctic Expeditions; he entered the University as a research student in geology in 1913; became a fellow of Clare College in 1923 and has been secretary to the Board of Research Studies for two years.

Two lists of successful candidates in the recent scholarship examinations have been published. An analysis of the awards of open scholarships and exhibitions shows that 35 are for natural science, 42 for mathematics and 113 for other subjects—classics, history, languages, etc. A further point of interest lies in the distribution of the successful candidates among the schools. It is often nowadays no easy matter to decide whether any place of secondary education is a "public school" in the generally accepted sense of the term. It is possible, however, to draw up an arbitrary list which will include those schools which the majority of educated people would call "public schools." The present writer has ventured to construct such a list, and has grouped the new scholars and exhibitioners according to it. The following figures have been obtained:

	Nat. Sci.	Math.	Other Subjects.
From Public Schools .	11	21	65
From other Secondary Schools . . .	24	21	48

Any deductions made from these figures are liable to severe criticism, but three hypotheses suggest themselves:

(1) The public schools divert the majority of their best scholars in directions other than scientific ones.

(2) The teaching of "other subjects" in the public schools is superior to instruction in them in the other schools.

(3) The teaching of science in other schools is generally superior to that in the public schools.

It is commonly believed in Cambridge that (3) is certainly partially correct in many cases. Perhaps it is time that the public schools gave the matter further thought.

ACCORDING to the report recently issued by the Secretary of the Rhodes Trust, the number of Rhodes Scholars in residence during the year 1924–1925 was 185, of which 96 were from the British Empire and 89 from the United States, 63 took up their scholarships for the first time. The present academic year started with 185 scholars in residence. From the table showing the distribution among subjects during the past year, it appears that 48 were taking natural science and medicine and 2 mathematics. Five Rhodes Scholars were awarded the degree of D.Phil., three of them being natural science students. Reference is also made to distinctions gained by former Rhodes Scholars, among whom are R. B. Brode, awarded a research fellowship by the National Research Council of America; H. W. Florey, appointed to a Rockefeller medical fellowship; and E. P. Hubble, who was awarded half the American Association for the Advancement of Science Prize for 1924 for his researches on nebulæ. Notice was received during the year of no less than 33 new books by Rhodes Scholars, of which only 4 have a bearing on science. The scholarships are to continue to be of the annual value of 400*l*. each. A site has been purchased at Oxford for the erection of a building to be known as "Rhodes House," which will be the residence of the Oxford secretary and will contain a library and a hall for the annual dinners of the Trust. Information as to the scholarships may be obtained from the offices of the Trust, Seymour House, Waterloo Place, London, S.W.1. In the United States application may be made to President Aydelotte, Swarthmore College, Swarthmore, Pennsylvania, in Canada to Mr. J. M. Macdonnell, National Trust Company, Limited, Montreal, P.Q., in Australia to Dr. J. C. Behan, Trinity College, Parkville, Victoria; in South Africa to Mr. P. T. Lewis, Court Chambers, Keerom Street, Cape Town.

APPRENTICES in H.M. Dockyards have to attend school for a certain number of hours each week, and any one who knows the Dockyard schools and the instructors in them is not surprised at the successes of the students, for no better scientific and technical education for youths is given anywhere in Great Britain. As, however, the apprentices are educated at the public expense with the view of their becoming shipwrights or fitters in the Dockyards, and as they have many decided advantages over students in technical schools outside, it seems scarcely just that they should be able to use these advantages to secure scholarships intended for science students generally. Judging from the list, just issued by the Board of Education, of successful candidates for Royal Scholarships and Free Studentships, and from the latest list of awards of Whitworth scholarships, there is little prospect of success for any candidate who has not been educated in a Dockyard school, particularly for scholarships in engineering subjects. Thus, there were seventy-one competitors for Group A (Engineering) for Royal Scholarships and Free Studentships in the 1925 examination, and each of the eleven successful candidates was a Dockyard apprentice. In the other groups—physics, chemistry, biology, and geology—all the successful candidates were from schools and colleges not in the Dockyards. Nearly all the Whitworth scholars in the last list were from the Dockyard schools, and so it has been for several years. This must be discouraging to teachers and students in other technical schools and colleges, and we suggest that the Board of Education might well give attention to the matter with the view of arriving at a more equitable adjustment of the awards. It was never intended that Royal and Whitworth Scholarships should be a special reserve for students in such institutions as H.M. Dockyards, where exceptional opportunities of preparing for them are enjoyed, both as regards the advantage of being given school time in working hours and as regards the practical and theoretical instruction afforded.

Contemporary Birthdays.

January 9, 1866. Prof Charles J Martin, C M G. F.R S

January 12, 1862. Prof. John G. Adami, C.B.E., F.R.S.

January 13, 1842. Sir Alfred F Yarrow, Bart, F.R.S.

January 13, 1843. Sir David Ferrier, F R S

January 13, 1858. Sir D. Orme Masson, K.B.E, F.R S

January 13, 1869. Sir Richard Paget, Bart.

Prof. J. G. ADAMI, Vice-Chancellor of the University of Liverpool, was born at Manchester Educated at Owens College in that city, he entered Christ's College, Cambridge, in 1880 In 1887 he became a demonstrator of pathology in the University, and afterwards John Lucas Walker student of pathology Prof. Adami was appointed Strathcona professor of pathology and bacteriology, McGill University, Montreal, in 1892, this post leading to important developments and highly appreciated issues of work whilst in Canada. President of the Canadian Association for the Prevention of Tuberculosis, 1909–12, he was president of the Association of American Physicians, 1911–12. Prof Adami has written much on the nature of inflammatory processes. A joint paper with the late Dr C S. Roy, "Contributions to the Physiology and Pathology of the Mammalian Heart," was published in the *Philosophical Transactions of the Royal Society.*

Sir ALFRED YARROW was born in London in 1842. Our cordial congratulations are offered on the occasion of his eighty-fourth birthday. He was educated at University College School, London. Beginning business as a shipbuilder and engineer at Poplar, he migrated to Clydeside in 1906, continuing, as the founder of the world-renowned firm which carries his name and flag, the building of merchant ships and supplying the multifarious requirements of British Navy craft. An early and generous benefactor to the National Physical Laboratory, the wider demands of science in general have found aid and maintenance through his munificence. So recently as 1923 Sir Alfred made a gift of 100,000*l*. to the Royal Society for administration as a research fund.

Sir DAVID FERRIER, emeritus professor of neuropathology, King's College, London, was born at Aberdeen in 1843, and thus has reached the ripe age of eighty-three years Graduating at Aberdeen in 1863, he studied as well at the Universities of Edinburgh and Heidelberg Sir David is specially identified with researches on the localisation of cerebral functions, begun fifty years or more ago. In presenting one of the Royal Society's Royal medals to him in 1890, the then president recorded that "we owe to Prof. Ferrier's experiments in monkeys, animals which he was the first to use for this purpose, the beginning and indeed the greater part of our knowledge of cerebral localisation in man. Broca located the centre for speech in the third left frontal convolution, but with this exception nothing was known of cerebral localisation in man until Ferrier commenced his experiments in 1873" By experiments upon monkeys Ferrier was able to map out the most important motor areas with great precision, and the results were eventually turned to practical account in cerebral surgery.

Early Science at Oxford.

January 11, 1683–4. A letter from Mr. Aston mentioned an Analysis of ye stone of ye bladder, given in to ye Royall Society, by Mr Lister, who affirms, that ye Lapidescent juices within ye body, are ye same with those which are without it; and that ye *Caput mortuum* of ye stone, will apply to a Magnet, like other pyrites.

The Minutes of what has passed in ye new Society of Dublin were read; They gave an account of severall discourses, of a differing nature, which have been read at their meetings; Wee shall in a little time, have copies of them. It was then ordered, that thankes should be return'd to ye gentlemen of that Society for ye favor of their correspondence, and that ye Minutes of this Society should constantly be sent them

An account was given of severall late distillations of brine, made by Dr. Plot and Mr Musgrave.

1686–7. Mr. Pit communicated an account of the peristaltic motion of the stomach, observed in a dog in July 1685 and also of lacteals arising from the stomach. He was desired to try if he could discover any lacteal veins in Birds.

January 12, 1685–6. Mr Flamsteed's Tide-Table for ye year 1686 was presented to ye Society, and Mr. LLoyd presented a Catalogue of ye Shells in ye Musæum Ashmoleanum.

Dr. Plot communicated a Table for ye keeping a Diary of Weather-journall by observing ye station of ye quicksilver in ye Baroscope, ye place of ye Spirits in ye Thermometer, the points and strength of the Wind; and ye state of ye Weather: together with an account of Weather-glasses exactly made and sold (as the table also is) by Mr. Jo: Warner, London.

January 13, 1684–5. Dr. Smith (in ye chair, in ye absence of ye President,) acquainted ye Society, that according to a MS. of Julius Africanus, belonging to Magdalen Colledge, (which MS. he thinks is about 200 years old,) ye citation of Vossius out of this Author, concerning ye making of Ignis Græcus, is exact.

A Cubicall measure, of a Quantity given, was proposed to be provided; Mr. Caswell, and Mr. Walker were desired to enquire, concerning ye making one, with it ye difference as to weight, between ye same measure of severall sorts of substances, as grains, earths &c of diverse kinds, may be examined, and ye quantity of water &c. exhaling from a given space, in a time given, may be found out; an account of which will make much toward ye clearing this quere, viz whether the water of ye Mediterranean is disposed of by way of vapor?

According to Mr. Charles Leigh, they have in the County of Lancashire an earth, never yet plowed in ye memory of man, in which (about 2 yards under ye surface) he has found severall grains of corn, not in ye least rotted; he has seen trees in it perfectly sound, it will preserve any kind of flesh; and (he thinks) it may make compleat Mummies.

He says, they have a Tobacco-pipe clay, which will dissolve in water, and take out any spot: that they have a fish, which (he thinks) is the sepia, for if they offer to catch it, it will immediately make ye water look as black as ink. Another fish in that Countrey, has a prickle on its back; with which, if the seamen are at any time prickt, ye part will certainly gangrene; this prickle, he says, is hollow, and is inserted into a little bladder, out of which ye poyson proceeds, after ye same manner as in Vipers

Mr Welsteed communicated an account of making turpentine, tar, rosin, and pitch near Marseilles, by Mr. Tho Bent M A. lately of Lincoln College.

Societies and Academies.

LONDON.

Geological Society, December 16.—W. D. **Lang** and L. F **Spath**: The black marl of Black Ven and Stonebarrow, in the Lias of the Dorset coast Pt. I. (W D. L.) The Black Marl Series of the Geological Survey includes Oppel's zones of *obtusus*, *oxynotum*, and *raricostatus*. The lowest part of the series—the Shales-with-Beef, has already been described in detail At least twelve horizons can be recognised in the Black Marl above the Shales-with-Beef; as well as two non-sequences. Pt. II (L. F S) New species of ammonites from the Black Marl are described Notes are also added by Dr. A. E Trueman on the Echioceratid ammonites; by Mr. L. R Cox on the lamellibranchs; and by Miss H. M. Muir-Wood on the brachiopods.

EDINBURGH.

Royal Society, December 21.—Sir J J **Thomson**: The intermittence of electric force. It is supposed that when a body is under the action of such a force, the increments it receives are each finite in amount and separated by finite intervals of time, the average interval of time being called the time interval of the electric field. For events which last over a large number of time intervals the results are the same as those given by the Classical Theory of continuous force, but for events which can happen in the very short time comparable with the time interval of field an entirely different treatment is required The path of an electron in an electric field would, on this view not be a curve of continuous curvature, but an irregular polygon with a very large number of sides. The intermittence of electric force would lead to some spontaneous dissociation of systems consisting of electrons and positively charged particles, and to the production of Rontgen rays when electrons passed near atoms, but these rays would be very soft unless the electrons moved so quickly that the time they were in the neighbourhood of the atom was comparable with the time interval of the electric field in the atom Since the time interval gets longer as the strength of the electric field diminishes, periodic electric waves cannot spread out indefinitely into space, for as they travel outwards the intensity of the electric field diminishes and ultimately gets so weak that its time constant is long compared with the period of the waves, the waves will be reflected back at this stage and thus the energy will be confined to a limited volume, and the shorter the period of the waves the smaller will be this volume This shows that the energy of light must travel in bundles which do not spread out as they travel through space The conception simplifies the dual theory of light recently brought forward by the author, as it ensures that the energy of the electrical waves in the unit of light should be constant as well as the energy of the quantum.—A R **Forsyth**: A chapter in the calculus of variations: maxima and minima for weak variations of integrals involving ordinary derivatives of the second order The paper constructs the tests for the possession of a maximum or a minimum, by integrals that involve first and second derivatives of an unknown quantity. The curve, representing the relation between the dependent variable and the independent variable, is subjected to completely arbitrary variations throughout its length, these being small in magnitude as regards position, direction, and curvature The tests are sufficient, as well as necessary, for the small variations specified.—A C **Aitken**: On the theory of graduation. A paper dealing with Prof E T. Whittaker's theory of the graduation of data A new method of solution is proposed which is better adapted for computation and also brings out a comparison with other extant methods of graduation.—C E **Weatherburn**: On triple systems of surfaces and non-orthogonal curvilinear co-ordinates.

SHEFFIELD

Society of Glass Technology, December 16.—W E. S **Turner**: The composition of glass suitable for use with automatic machines A survey was made of the whole field of glass compositions which have been used, particularly for glass bottles, from the time of the Roman glass makers down to the present day. The introduction of the automatic machine has much limited the range of compositions available For example, in using a number of types of machines the percentage of lime in the glass cannot be raised safely above 10 per cent., whereas in some of the glass used on the continent and worked by hand 20 per cent sometimes occurs The factors which decide the limits of composition are the size of the article, whether colourless or coloured; the method by which the machine is to be charged, that is to say, whether by suction or by gob feeding; and finally by the type of machine itself. Scientifically, the factors of importance are the viscosity of the glass, the rate at which the viscosity changes with temperature, the heat conductivity and heat radiation.—Violet **Dimbleby** and W E. S. **Turner**. The relationship between the durability and the chemical composition of glass Tests were made of glasses of similar type in which soda was replaced successively by lime, magnesia, alumina, titania, zirconia, barium oxide and boric oxide. In all, 70 to 80 individual glasses were prepared, and the action of the four reagents, namely, boiling water, hydrochloric acid, sodium carbonate and caustic soda solution, were tested.

CAPE TOWN.

Royal Society of South Africa, October 21.—P. R. v.d. R **Copeman**: Note on the decrease in acidity during the ripening of grapes. The most important changes occur in the sugar and acid content of the juice. The acidity, as determined by titration, decreases during ripening, and when the logarithm of the acidity is plotted against the time, a straight line is obtained. The concentration of acid varies with the time, and the rate of decrease is proportional to the existing concentration. The acidity at any given time depends upon the variety of grape The rate of decrease of acidity is independent of the variety, but is dependent upon some seasonal variation The rate at which grapes ripen during any given season is independent of the variety At maturity the decrease in acidity becomes practically negligible.—Alexander **Brown**: An extension of Ceva's theorem to polygons of any number of sides For a polygon of $2m$ sides it gives $m-1$ relations, and for a polygon of $2m+1$ sides it gives m relations. Various special results already known can be derived as particular cases.—L. P. **Bosman**. The hydrolytic properties of certain amino-acids. Falk and Nielson state that the amino-acids glycine, alanine, leucine, aspartic and glutamic, bring about the hydrolyses of esters such as methyl acetate, ethyl butyrate, and olive oil. The actual hydrolyses cannot, however, be attributed to the fact that these acids contain the amino-group. The acidity of the medium seems to be the cause of the hydrolyses.—D. B. **Swart**: Note on the South African marine mussel, *Mytilus Meridionalis*, Krauss (1848). *M. Meridionalis* is established beyond all doubt as a distinct species.—H G **Fourcade**: (1) On instruments and methods for stereoscopic surveying (2) The optical transformation of projections and its application to mapping from air photographs. (3) On some conditions for the accurate vision of stereoscopic pictures

ROME

Royal Academy of the Lincei, November 1.—**G. Armellini**: An apparent oscillation of the solar diameter. Experiments carried out in the Royal Campidoglio Observatory. Measurements made in three Italian observatories in 1924 give, for the sun's diameter, values lower than those obtained in 1923. Support is thus furnished to Hilfiker's and Lane's hypothesis that the sun is a pulsating star.—**F. Zambonini** and **G. Carobbi**: Double sulphates of the rare earth and alkali metals (iii). Double sulphates of lanthanum and sodium. Investigation of the isotherm for 25° indicates the formation of the stable compound, $La_2(SO_4)_3$, Na_2SO_4, $2H_2O$.—**F. Zambonini** and **R G Levi**: Researches on the isomorphism of the molybdates of rare earth metals with those of calcium, strontium, barium, and lead. Röntgenographic analysis shows that the compounds $CaMoO_4$, $SrMoO_4$, $BaMoO_4$, and $PbMoO_4$ possess identical crystalline structures.—Mineo **Chini**: Plane lines, for which the length of the arc is given in polar coordinates, as a function of the anomaly of the extremity.—**G. C. Evans**: The simple potential, and Neumann's problem.—Mentore **Maggini**. The orbit of the binary system OΣ 535, deduced from interferometric measurements.—**V. Ronchi**. The ocular interferometer.—Rita **Brunetti**: The effect of chemical linking on the energy of intra-atomic levels.—**A. Pontremoli**: The orientation in a constant electric or magnetic field in the hypothesis of molecular anisotropy.—**L. Tieri**: Determination of Avogadro's constant by means of doubly refracting solutions of dialysed iron. Results are obtained which show that even liquids which under the ultramicroscope appear to contain in suspension granules of only one type, actually contain granules of different magnitudes. There results, therefore, increased condensation of the granules at the bottom of the liquid, and consequently, for the lower layers, greater double refraction than corresponds with Laplace's law.—Luigi **Rolla** and Giorgio **Piccardi**: Chemical statics of electronic phenomena.—Mario **Amadori**: Products of the condensation of glucose with *p*-phenetidine.—Michele **Giua**: Influence of substituents on the formation and stability of various cyclic compounds. In connexion with the nuclear tension of coumaranone and coumarandione compounds, the condensation of malonyl chloride with β-naphthol has been investigated.—Pietro **Saccardi**: The nature of melanogen. When injected into the animal organism, pyrrole does not pass unaltered into the urine, but is converted by oxidation in the organism into a melanogen which yields an azo-compound different from that furnished by pyrrole.—Tullio **Carpanese**: The epidote of Monte Rosso di Verra (Monte Rosa group). This mineral, of specific gravity 3·343, exhibits the crystallographic constants, $a:b:c=1{\cdot}5803:1:1{\cdot}8045$, $\beta=64^\circ\ 34{\cdot}5'$, and a composition in good agreement with the formula $HCa_2(Al, Fe)_3Si_3O_{13}$.—Cesare **Artom**: Obligatory correlations of true tetraploidism (giantism and cellular magnitude).—Gustavo **Brunelli** and Ettore **Remotti**: The physiologico-etiological significance of the secondary sexual characters in Gambusia.

SYDNEY.

Royal Society of New South Wales, November 4.—**J. C. Earl** and **V. M. Trikojus**: The constitution of australol. The identity of the solid phenol, australol, isolated from certain eucalyptus oils by the late Mr H. G Smith, with *p*-isopropyl phenol, has been established. For the purpose of comparison, *p*-isopropyl phenol was prepared synthetically by the following scheme of reactions: magnesium phenyl bromide + acetone ⟶ phenyl methyl carbinol ⟶ isopropenyl benzene ⟶ cumene ⟶ sodium cumene *p*-sulphonate ⟶ *p*-isopropyl phenol.—**A. R. Penfold**: The essential oils of *Melaleuca linariifolia* and *M. alternifolia*. Both these tall papery-bark tea trees follow the water-courses of the coast districts of N S Wales and southern Queensland, the former being abundant around Sydney, whilst the latter is plentiful at Copmanhurst on the Clarence River. Terpinenes, cymene, d-a-pinene, cineol, sesquiterpenes (cadinene), and terpinenol-4, with a little sesquiterpene alcohol, are the principal constituents of the essential oils.—**Leo A. Cotton**: Note on the earthquakes at Murrambateman during March and April 1924, and January to April 1925. Although the continent of Australia lies outside the two great earthquake belts of the world in which 95 per cent. of all recorded shocks occur, there are certain areas which are subject to occasional earthquakes. The Yass district is one which has from time to time been shaken, but there is no previous record of such a seismic spasm as that which affected this district during the months of March and April 1924. Altogether some nine or ten shocks were recorded in this interval. The first earthquake was the most pronounced, and the information secured from many residents in the district show that the isoseismals have a pronounced L-shaped distribution which is attributed to movement along two faults which act as partial boundaries of an unstable earth block. A recurrence of seismic activity in the district took place during the period January to April in the following year (1925). Five shocks were recorded in this interval.—**M B Welch**: The identification of the principal ironbarks and allied woods. Australia's most valuable hardwoods for heavy constructional work, railway sleepers, poles, etc., are the ironbarks. It is, however, very difficult to separate these woods from certain timbers known as grey gum, which are often substituted for the former. Certain differences exist, however, and these are described.

Research and Education in Agriculture.

IT is difficult for the lay mind to appreciate the possibilities of an architectural venture until at last the scaffolds are withdrawn and the finished building stands forth for all to see—to praise or to blame. It has been thus with the steady building up of our present system of agricultural research and education. It is only now, as the scaffolds are being slowly removed, that we can realise to the full the scope of the edifice which it has been sought to erect.

The Report recently issued by the Intelligence Department of the Ministry of Agriculture[1] is an interesting document, in which it has been possible perhaps for the first time to give the reader a complete picture of the machinery by which it is hoped to bring scientific knowledge and scientific method to the direct aid of the farmer. It will be a matter of surprise to many—no doubt accustomed to think that England still lags far behind other countries in the matter of financial support to agricultural research and education—to find on what a substantial foundation the system has been built. The plans, too, have been well drawn, for they allow of harmonious expansion in several directions, and there can be no gainsaying that the system as a whole holds much promise for the future.

It will be apparent that one of the corner-stones of the whole structure is research—and it is satisfactory to be able, in parenthesis, to add that the farmers themselves have been second to none in their anxiety that this stone should be well and truly laid. Not only are annual grants to a total exceeding 104,000*l.* made to twenty-one research institutions in England and Wales—each charged with definite lines of inquiry—but also grants now amounting to 31,400*l.* are made to fourteen advisory centres in order largely to provide for research into purely local problems.

It is very satisfactory to note that the advisory system has been considerably strengthened—the grants have been increased by 13,650*l.* since 1921–22, and advisory economists have now been appointed to the majority of the centres. Perhaps the chief merit of the advisory scheme is the tacit recognition of the importance of stimulating the research spirit in connexion with the teaching departments. It follows that a far-reaching effect of the strengthening of the personnel at the colleges consequent on the appointment of the advisory officers is that the teaching staff have greater opportunities for specialisation and for conducting independent research.

Grants to agricultural departments of the universities and to agricultural colleges for higher education are made to fifteen institutions to a total of 48,500*l.* There is less disparity between the grants made to the different teaching centres—although even here it is appreciable—than to institutions charged primarily with research. In the latter case a large disparity is almost inevitable, since the several research institutions have very different terms of reference demanding very different staffing and equipment. As time goes on it is, however, to be hoped that it will be found possible rather to level up the grants to the several institutions than to accentuate the differences further—and this tendency should be applied alike to research and educational grants. Over-wide disparities in the distribution of public funds are at all times undesirable, and if carried to excess might possibly stimulate something much less desirable than healthy rivalry.

---

[1] Ministry of Agriculture and Fisheries. Report of the Work of the Intelligence Department of the Ministry for the three years 1921–24 Pp 163. (London: H.M. Stationery Office.) 5s net.

Grants to the counties have totalled 150,000*l.*, making the gross expenditure on county work, in part financed from local funds, 224,000*l.* Agricultural organisers are now attached to practically all the counties in England and Wales, while in a large number of counties there also exists the nucleus of a sound educational staff. The provision of farm institutes in the counties has been increased to fourteen.

There is thus provided a complete chain from research to education aiming at bringing the maximum of assistance to the farmer. The organisation of the whole system, however, presents difficulties, for not only are a large number and wide range of workers involved, but administration also falls to a number of different bodies—the Ministry of Agriculture, the governing bodies of colleges, universities and research institutions, and the county authorities. In regard to some aspects of the work responsibility is also, in part at least, delegated to advisory committees or councils, while trade interests and opinions have frequently to be considered.

The Ministry of Agriculture has sought to coordinate the whole work by setting up standing conferences, such as, for example, those of the advisory pathologists and advisory chemists, and from time to time calling larger conferences of research, college, and county workers. Regional conferences of all the workers in the counties associated with the different advisory centres have also become general, and more and more are fulfilling the most important part in the smooth working of the machine. There is perhaps real risk, however, that some of the measures adopted may tend towards a too great standardisation in respect of the functions and duties of both institutions and individuals, rather than towards co-ordination in the highest sense.

In research a certain amount of overlapping can never be avoided, and since method and individuality go for so much, is perhaps rather to be encouraged than the reverse. The consequences could only be disastrous if research came to be considered as almost the sole prerogative of the research institutions and of the advisers, and if the drawing up, or criticism, of schemes of research or inquiry were deemed only to be the concern of the "official" research workers. In a loosely knit together system the success of which depends solely on good-will—and since the system is primarily intended to serve the interests of a profoundly complicated industry—the ideas of practical workers in close touch with the farmer should be regarded as of at least equal value in formulating profitable lines of research to those of the research workers themselves.

It is, therefore, of the utmost importance that the constitution of all conferences and committees—if only remotely connected with the administration of any part of the scheme—should always be such as to imply nothing in the nature of prerogatives. Moreover, the terms of reference under which an institution or an individual worker acts, no matter how restricted their scope, are surely not intended to imply the possession of a monopoly; consequently—and in order to dispel completely the possibility of any such views being held—the greatest possible encouragement should be given to any independent worker of proved capacity to proceed with an attack by methods which seem good to him on a problem to which he is attracted, even if the investigation comes within the category of subjects dealt with at one of the research institutions. Any tendency in the opposite direction should be rigidly guarded against, for if allowed to develop it would assuredly shatter the stability of the whole fabric, and would certainly tend to stultify originality, which is the life-blood of successful investigation.

There is very considerable evidence in the report to show that scientific information is, in fact, not only being put into the farmers' hands, but is also being used to good advantage. Perhaps the most significant figure quoted in this connexion is that 6782 persons attended evening classes during the year 1923–24, while the success of the formation of agricultural discussion societies in the counties is another excellent augury for the future. The value of these classes and societies will, moreover, increase in proportion as the number of young men with practical farming as their objective pass through the colleges and farm institutes.

The various schemes of organisation pressed forward by the Ministry have amply justified themselves. This is well seen with reference to the recent great advances made in poultry keeping in Great Britain and in relation to various aspects of the horticultural industry. In some ways the most significant work of organisation is that connected with certain features of the administration of the Destructive Insects and Pests Act. Reference is made to the inspection and certification of growing crops of approved immune varieties of potatoes and to the wart disease immunity trials conducted under the auspices of the National Institute of Agricultural Botany at its Ormskirk station. These constitute relatively new departures, which eventually will almost certainly be applied in principle to other crops with beneficial results of a magnitude that at present we can but dimly foresee.

By no means the least important of the activities under the general guidance of the Ministry are the various live-stock improvement schemes. The report before us is evidence in particular of the fruitful results of the comparatively recently introduced milk-recording scheme. The recorded herds show a substantial increase in the average yields per cow from year to year, and, what is of greater importance, a marked improvement in the proportion of high-yielding cows in the several herds, due to the steady weeding out of the poorer milkers. This is a scheme which has an altogether greater value than is indicated merely by the convincing statistics given—for more than any other educational activity it has taught the farmer the value of accurate records, a lesson which he must come eventually to apply to all his breeding and perhaps to most of his practices.

From the scientific point of view, the achievements have important implications, for they show the necessity of testing and checking the validity of show-yard criteria in respect of all live-stock. At present the breeding societies, assisted by the Ministry, base the selection of sires almost wholly on show-yard criteria, and the excellence of the selections made is sought to be substantiated in a paragraph—which is perhaps prematurely thrasonical—alluding to the successes of stock by premium bulls at the shows.

The whole question of the merits of one breed compared to another, and of one type of animal within the breed to another, is intimately connected, however, with economy of conversion of feeding-stuffs. It would perhaps be wise, in view of the teaching of the milk records, to initiate well-planned local schemes of experimentation, at carefully selected centres, designed to obtain trustworthy data on the economic suitability of different types of animals for the different conditions obtaining. This should be done before going too far to encourage breed societies run on the unproven assumption that show-yard criteria afford the correct basis for selecting sires competent to beget progeny with the highest possible money-earning capacity when employed as ordinary farm stock in the districts severally served by the societies.

The History of Engineering.

A History of Engineering. By A. P. M. Fleming and H. J. Brocklehurst. (The Histories of English Industries Series.) Pp. vii+312. (London: A. and C. Black, Ltd., 1925.) 12*s*. 6*d*. net.

THOUGH there are many biographies of engineers and historical works in various branches of engineering, no attempt appears to have been made to write a general history of engineering. The reasons for this are perhaps not far to seek. No one but an engineer could write such a book, and engineers, as a rule, are actively engaged in the exercise of their profession and are concerned more with the present and the future than with the past. It is true many engineers possess the necessary literary ability and a few the wide knowledge and experience, but the opportunities for historical studies are but few. A step in the right direction was taken a few years ago when the Newcomen Society was founded, and the researches by its members will prove a mine of information for the future historian. But the subject is a vast one; the materials are there in profusion, and the task of selection is by no means easy. Of the sources of information, none are perhaps of more value than the transactions of the various engineering societies, the addresses of the presidents often containing historical reviews of great importance; those of Sir John Rennie in 1846 and of Sir William White in 1903 to the Institution of Civil Engineers being two notable examples.

While no general history of engineering exists, historical notes are often given in text-books, and there is ample evidence that in the profession there is a growing sense of the value of the records of the past. France and England have possessed museums illustrating invention and engineering for many years, German engineers supported whole-heartedly the building up of the Deutsches Museum in Munich, and energetic action is now being taken to form a National Museum of Engineering and Industry for the United States. This will probably take the form of a central museum at Washington, with smaller museums of an educational character in some of the great industrial centres. This is a movement which will be watched with growing interest. The committee entrusted with the task of inaugurating the American Museum includes representatives of the four Founder Societies of Civil Engineers, Mechanical Engineers, Mining Engineers, and Electrical Engineers. For their president they have Mr. Samuel Insull, of whom it has been said "no ship ever stranded which had him for its helmsman."

Nearly all engineering can be included in four groups relating to transport, communication, power, and production. The story begins with the earliest of tools, the making of sledges and the use of metals. It includes the construction of canals and harbours, bridges and aqueducts by the Chinese, the Egyptians, and the Romans, who, working with the simplest appliances, raised those monumental works which claim our profound admiration to-day. While admitting the absorbing interest of the study of the engineering feats of the ancients, it is modern engineering which has changed the face of the world and the habits of nations. Modern engineering had its birth with the steam engine in the early part of the eighteenth century, and its scope is indicated by the definition accepted after much deliberation by the American Society of Mechanical Engineers in the statement: "Engineering is the science of controlling the forces and utilising the materials of nature for the benefit of man and is the art of directing and organising human activities in connexion therewith." The definition breathes a spirit of service worthy of the noble heritage of the engineer; a heritage of which we cannot know too much. Each generation has produced its pioneers, and the young engineer will find in their lives a source of inspiration. The objects of our engineering museums include the preservation of historic works, but they might also well include the publication of adequate and impartial histories of the progress of engineering.

Like all science, engineering is international, and the improvements and discoveries of each nation are available for all. Yet there is room for the histories of nations as well as of mankind, and the book which has led to these remarks is a history of engineering devoted mainly to the story of engineering in England. It has chapters on docks and harbours, canals, roads and bridges, steam, railways, iron, gas and electricity, as well as a short chapter on ancient engineering. The writers, however, have mainly kept to the old well-beaten tracks, and we are thus once again brought into the company of Brindley, Newcomen, Stephenson, Cort, Watt, Hedley, and Faraday. The story retold is of immense importance, but we should have been glad of more information regarding the growth of the great industries these pioneers promoted. Of thirty-four pages given to the chapter "The Age of Steam," thirty are devoted to Savery, Newcomen, Watt, and their contemporaries, and four to the steam turbine. We nowhere find the names of Perkins, Donkin, Hicks, Joule, Marshall, Elder, Kirk, Rankine, Willans, or Yarrow. The compound and triple expansion engines, the high-speed engines working with high pressures, were all very important improvements, and half a century ago numerous engineering firms were employed almost solely in their production. We were the makers of steam engines for the whole world, and the history of this industry has never been written.

As introductory essays to the study of engineering history, the sketches in the book are well worth reading, but much more is required than this. The sense of proportion is one of the essential qualifications of the historian of engineering if he is to endeavour to follow in the footsteps of Gibbon, who with a wide and intimate knowledge of his subject possessed the power of mastering his materials and of condensing them into a broad and well-filled narrative in a manner which has never been surpassed. We speak of the age of steam, the iron age, the steel age, the age of machinery, the age of electricity, and the age of invention, but there are no such separate ages; they are all included in the age of modern engineering, and the telling of that story still awaits its Gibbon.

The Psychology of Juvenile Crime.

The Young Delinquent. By Prof. Cyril Burt. Pp. xx+643. (London: University of London Press, Ltd., 1925.) 17*s.* 6*d.* net.

PROF. BURT'S aim in this important study is primarily practical; he wishes to afford to teachers, probation officers, and others, aid in the investigation and treatment of young offenders. His practical advice, however, is based upon an exact and scientific study of data collected by himself in the course of his work in connexion with the schools of the London County Council, and he brings to bear upon the treatment of his problems a breadth of outlook very rare in the previous studies of the etiology of crime. Very frequently these have been vitiated by over-emphasis of selected cases, by preconceived notions as to the relative importance of heredity and environment as determinants of human conduct, by the absence of a sound anthropological and psychological basis.

Prof. Burt's work undoubtedly avoids these defects. His method is to take a sample collection of two hundred consecutive cases of juvenile delinquency, to study these intensively, and to check his conclusions by a study of a control group of four hundred cases taken from the non-delinquent population of children of the same age and social class, living in the same streets and attending the same schools. In each case he studies carefully the home circumstances, the family history, the physical and mental condition of the child concerned. His main conclusions may be briefly indicated. As to hereditary factors, he shows that the notion that crime can be as such inherited is due to crude and antiquated ideas as to the existence of an innate moral sense, and to the fact that most writers on the subject have adopted the method of citing conspicuous case histories and selected family trees with crime occurring in all of them. His own elaborate statistical study shows that cases of sporadic crime are far more usual than those with criminal lineage. It is true that intellectual and moral defects have a high frequency among delinquent families, but the figures given approach closely those for defective discipline and vicious surroundings, and it is therefore possible that we are dealing rather with contagion than biological heredity. We shall see later that a direct hereditary relation is asserted of crimes based upon an exaggeration of certain instincts. But even in these cases the instincts underlying them are not as such criminal and are never the sole causes of the crimes committed. All that can be said at the most is that what is inherited is a vague congenital enfeeblement which may affect the temperament, intelligence, and physique as a whole, and may in certain circumstances find expression in tendencies to crime.

It is one of the many merits of Prof. Burt's work that he avoids any undue separation between environmental and hereditary factors. It is not any given situation or environment that makes a man a criminal, nor is crime due to hereditary structure or equipment taken in itself. In all cases we have to deal with a subtle and intricate personal response to a given situation. Such response is never merely mechanical, never a passive effect of an external cause, but the active expression of the mind of the individual in relation to his environment. It is necessary, accordingly, to study both the innate equipment and the environmental condition of the criminal, but the two sets of factors must not be sharply separated from one another and pitted against one another in the simple manner so common in the literature of the subject. Moreover, in regard to the environmental factors, it must be remembered that owing to their complexity they can scarcely ever be fully and adequately determined, and that though, for purposes of investigation, each factor may be studied in abstraction from the rest, yet in fact they interact and modify one another in the most intricate and perplexing manner.

The use of mathematical or statistical expressions often gives to results of social inquiry an appearance of precision quite unwarranted by the crude data upon which they are commonly based. Prof. Burt uses his statistical methods with the caution which we have learnt to expect from him. The coefficients of association he arrives at for environmental factors are: for poverty, 0·15; for defective family relationships, 0·33; for vicious homes, 0·39; for defective discipline, 0·55; for conditions outside the home, including unemployment, uncongenial work, influence of associates, 0·29. He shows clearly that the commonest and most disastrous conditions are those that centre about the family life. As regards physical characteristics, Prof. Burt confirms the conclusion, reached by Goring in relation to adults, that the criminal conforms to no definite physical type. On the other hand, defects of development and general physique are more common among delinquent than among non-delinquent children of the same class. In general intelligence delinquent children have a lower average mental ratio than the non-delinquent. More serious is the fact that the "educational ratio" of the former which measures their attainment as distinguished from their ability is only 81 per cent., that is, at the age of ten their attainments are on an average those of a child of eight, and that of those who have left school, more than half are under the level of Standard V.

The least satisfactory portion of the book seems to me to be that devoted to the study of the temperamental conditions of crime. Prof. Burt finds a correspondence between categories of delinquencies and the usually accepted classifications of instincts, and this leads him to stress the instinctive origin of certain types of crime, especially those connected with sex, violent temper, wandering, and impulsive theft. But there is, as I think, at present too much divergence of opinion both as to the nature and classification of human instincts to make such a treatment really fruitful. Some examples will make this point clear. Prof. Burt studies cases of theft in connexion with the instinct of acquisition, but it may be and has been seriously doubted whether acquisition in man is really instinctive. The processes of acquiring are generally connected with the satisfaction of other instincts, for example, nutrition and sex, and objects connected with these and other instincts may by well-known psychological processes of assimilation and acquirement of meaning come to have value attached to them. Cases of so-called "objectless" hoarding can generally be shown by analysis to have an interest real enough to the subject concerned, though meaningless to the external observer.

So again, I doubt whether self-assertiveness and self-submission can be correctly spoken of as instincts. They seem to indicate rather degrees of strength with which the instincts generally express themselves in different individuals. If this be so, the explanation of cruelty given by Prof. Burt as due to an exaggeration of the instinct of assertiveness is only true in the sense that the intensification of any instinct, notably of combativeness and sex, may lead to a condition of absorption causing disregard of the pain of others. Again, to assert that sex-differences in relation to crime are connected with the different strengths of the instincts in the two sexes seems, in the present state of the psychology of the instincts, weak methodologically. For example, the explanation suggested on these lines of the greater frequency of cases of theft among boys than among girls, would have been better grounded if Prof. Burt had been able to produce independent evidence to show that women are innately less acquisitive than men. One conclusion certainly emerges from this discussion, namely, the urgent need there is at present for a really scientific classification of the human instincts. The volume before us is the first of a series of three. The other two will be eagerly awaited by all students of social science and education. MORRIS GINSBERG.

The Structure of the Earth.

Der Aufbau der Erde. Von Dr. B. Gutenberg. Pp. viii + 168. (Berlin: Gebrüder Borntraeger, 1925.) 9 gold marks.

THE work under review is a general survey of the known results relating to the condition of the interior of the earth. In most cases the theories discussed are not developed in detail, but summaries of the data and the main conclusions are given. Accordingly a very large amount of material has been compressed into a small space. It may be said that the main use of the book is to facilitate reference to original investigations; in this the reviewer speaks from his own experience. Perhaps the greatest difficulty that besets geophysics is that its literature is scattered through so many periodicals. It is easy to think of eight British journals that have contained important geophysical (apart from meteorological) papers during the past ten years, but in Germany the confusion is even greater. The bibliography in this book refers to twenty papers by the author himself, in nine periodical and several non-periodical publications; and the total number of German periodicals including geophysical papers is such that some convenient summary, with references, such as Dr. Gutenberg's book affords, is essential to any one wishing to know what work has actually been carried out. Unfortunately there are signs of insufficient verification; near the beginning of the bibliography we find "Cooker" for "Coker," without indication that the associated Adams is F. D. and not J. C. or L. H.; and incorrect initials are then attributed several times to L. H. Adams. But the labour involved in compiling a 14-page bibliography in the circumstances must have been enormous, and the author deserves our gratitude, especially as he has done justice to countries and languages not his own.

The seismological parts of the book merit the greatest attention. The illustrations on pp. 7, 8, 25, 30, and 96, showing typical seismograms for various epicentral distances, are a valuable feature. Accounts are given of the determination of the wave-velocities at various depths from the times of transmission, and also of Zöppritz's method of amplitudes, the actual application of which is largely due to Dr. Gutenberg. If the velocity of a compressional wave, say, increases steadily with depth, the amplitude of the motion it produces on emerging at the surface will vary smoothly with distance from the origin; but if the rate of increase of the velocity with depth changes suddenly, the amplitude will also change suddenly. As a rule, observations of the same shock at many stations are not collected, and use was made, instead, of the ratios of the amplitudes of the primary and first reflected waves for different earthquakes; this plan has obvious drawbacks, but it has the advantage that all the observations were made on the same instrument. The method is very sensitive, and its use probably lies mainly in filling in the finer details of the variation of velocity, the times of transmission giving the general outline. A rather sudden decrease of the velocity of the compressional waves, at a depth of about 0·6 of the radius, was inferred from the time-curves by R. D. Oldham in 1906. Gutenberg shows that this is confirmed by the smallness of these waves for distances of 110°-140°, while their reappearance at minimum deviation is indicated by the large amplitudes found at about 140°. That the central core below this depth is truly fluid is indicated by the absence of distortional waves at greater distances.

An account is given of the "individual P-waves" of A. and S. Mohorovičić—compressional waves from foci within the outer granitic layer, which travel directly from the focus to the surface, whereas the normal P-wave travels down to the basic rocks below and up again. These and explosion waves give valuable information about the surface layer, and the author then discusses the surface waves at length. The estimate of the thickness of the surface layer based on these last is, however, vitiated by a confusion between wave-velocity and group-velocity.

Other chapters deal with the figure of the earth, the internal distribution of density, chemical composition, the cooling of the earth, and the structure of the atmosphere. The age of the earth and tidal friction are not discussed, but the bodily tide is considered at some length. The author has misunderstood the situation with regard to the explanation of the annual variation of latitude, for he suggests that the work of the present reviewer on this subject was an attempt to improve on that of Schweydar, which was already perfect. Actually my work was published in 1916, Schweydar's in 1919 (of course, independently), and in both there remains a considerable discrepancy between theory and observation.

Dr. Gutenberg's book is an important contribution to geophysics, both for its own content and for the aid it gives in the search for other literature.

H. JEFFREYS.

Our Bookshelf.

The Dinoflagellates of Northern Seas. By Dr. Marie C. Lebour. Pp. vii + 250 (35 plates). (Plymouth: Marine Biological Laboratory; London: Dulau and Co., Ltd., 1925.) 12*s.* 6*d.* net.

A SHORT account is given of the general morphology of the Dinoflagellata, in which the terms afterwards employed are clearly explained, the various modes of nutrition are considered, and notes are added on the reproduction and habits. Dr. Lebour expresses the opinion that a large proportion of what are now regarded as species may prove to be merely phases in the life-history of other species. An outline classification showing the families and genera precedes the systematic account, in which a short description of each genus and species is given, and the characters of the species are illustrated by one or more line drawings—those on the 35 plates being original. The methods of collecting and examining dinoflagellates are briefly described, a list of memoirs on the sub-class is appended, and there is a full index.

Dr. Lebour set herself the task of making as complete a survey as possible of the dinoflagellates which are known to occur in northern seas, and she has accomplished the work in a highly successful and critical manner. Her memoir will be warmly received by all who are interested in these organisms.

Kelvin the Man. A Biographical Sketch by his Niece, Agnes Gardner King. Pp. xv + 142 + 12 plates. (London: Hodder and Stoughton, Ltd., 1925.) 7*s.* 6*d.* net.

BY the many admirers of Lord Kelvin this book will be welcomed. In 1910, Silvanus Thompson wrote the official biography. In the preceding year, Kelvin's sister, Mrs. King, wrote "Lord Kelvin's Early Home," which gives a delightful picture of him from childhood to adolescence as a member of a singularly gifted and harmonious family. Silvanus Thompson says that he purposely abstained from trenching on that narrative, which brings the story of Lord Kelvin's life to 1849. The gap in the story of his personal and family life from 1849 onwards is now filled up by this book written by his niece, Agnes Gardner King She presents a very pleasant home picture of the great physicist, showing a very human and lovable side of his character. In the introduction, Sir Donald MacAlister says: "The testimony of an eye-witness in intimate touch with his home, and capable of putting down in simple and vivid words what she saw and heard, will crown as with a garland of home-grown flowers the Centenary Memorial raised to his scientific fame."

Intermediate Light. By Dr. R. A. Houstoun. Pp. x + 228. (London: Longmans, Green and Co., 1925.) 6*s.*

ENCOURAGED by the favour shown by advanced students to his "Treatise on Light," Dr. Houstoun has now produced an elementary book on the same subject. It is broadly of University Intermediate or Higher Certificate standard, but the author, it is pleasant to note, is at no pains to conform to the syllabus of any particular examination. The book, therefore, contains matter seldom found in the ordinary elementary textbook. Colour and colour vision, for example, claim more space than is customary, and the historical references are both less meagre and less stereotyped than usual. At the same time, examination requirements are by no means overlooked, and a collection of questions from various public examinations forms a useful appendix. Other noteworthy features are the numerous and well-planned practical exercises and the new illustrations of familiar principles which are selected whenever possible. The diagrams and production are excellent; in fact, we have noticed nothing more reprehensible than a split infinitive There is no doubt that the book deserves and will enjoy a wide popularity.

Prof. Dr. Paul Pfurtscheller's Coloured Zoological Wall-Plates. Plate 32: The Common Gnat (*Culex pipiens*). Insecta, Diptera II. 4 ft. 8 in. × 4 ft. 3 in (London: W. and G. Foyle, Ltd.; The Hague: Martinus Nijhoff, 1925.) Unmounted, 10*s.* 6*d.*; mounted, with rollers, 16*s.*; mounted, with rollers, varnished, 17*s* 6*d.*

THIS is an excellent plate, lithographed in colours, illustrating the external features of the larva (from the dorsal aspect) and the pupa and the female winged gnat (as seen from one side). The important features are clearly displayed, the parts being skilfully arranged so as to exhibit as much as possible. A portion of the wall of the abdomen of the imago is shown cut away to permit representation of parts of the stomach, intestine, Malpighian tubes and ovary. In the fourth figure the head of a female and the mouth parts are drawn on a larger scale. It is ungracious to ask for more on such a full plate, but a drawing of the head of a male would have been helpful for comparison with that of the female.

Bacteriology. By Prof. Carl H. Browning. (Home University Library of Modern Knowledge.). Pp. 256. (London: Williams and Norgate, Ltd.; New York: Henry Holt and Co., 1925.) 2*s.* 6*d.* net.

WE think that Prof. Carl Browning has been extraordinarily successful in presenting a general outline of the principal facts concerning bacteria in a simple and concise manner suited to the general reader. The whole range of bacteriology is dealt with—history, the microscope, methods of investigating bacteria, and their rôle in Nature and in the causation of disease. Subjects such as antitoxins and the toxin-antitoxin reaction, complement fixation, the Weil-Felix agglutination reaction in typhus fever, ultra-microscopic organisms, the bacteriophage, immunity and chemotherapy, are all considered, and their presentation is such that any one reading the accounts of them will have a very good general idea of what they are and mean.

Geometry for Beginners, as far as the Theorem of Pythagoras. By J. G Bradshaw. Pp. vii + 99. (London: Longmans, Green and Co., 1925.) 2*s.* 6*d.*

IN many respects an excellent little book, in which blank pages are left for the pupil to insert his own proofs of the simpler propositions which are treated as riders. It is not in accordance with modern views, however, that beginners should be asked to learn the time-honoured proofs for congruence and parallels.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Further Studies of Sun-fishes made during the *Dana* Expedition, 1921-1922.

IN the columns of NATURE for March 17, 1921, I gave an account of the development of the sun-fishes so far as it was known up to that date, based on the investigations made during the first *Dana* expedition, in the course of which I was able to study the larvæ in a living state.

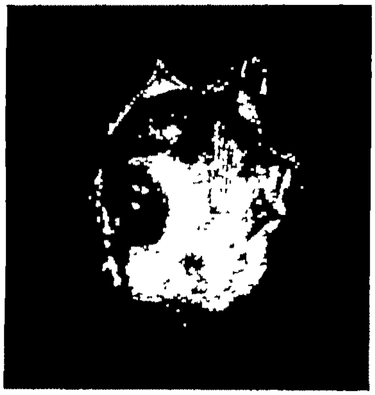

FIG. 1.—*Mola rotunda*, the short sun-fish. Specimen 5 mm. in length (*Dana*, St. 1238, 26° 13′ N., 78° 48′ W.).

The article described briefly the development of the two species, *Ranzania truncata* (the oblong sun-fish) and *Mola lanceolata* (the pointed-tailed sun-fish).

In a later and more detailed work, published by the Danish Commission for Investigation of the Sea ("Meddelelser fra Kommissionen for Havundersøgelser," Serie Fiskeri, vol. 6, No. 6, Copenhagen, 1921) I gave a further account of the development, and showed also that there are in the North Atlantic area *three* species of sun-fish: namely, in addition to the little Ranzania, not *one*, but *two* species of the large sun-fish proper (Mola), these being the ordinary tailless *Mola rotunda* (the short sun-fish) and the rarer form, *Mola lanceolata* (the pointed-tailed sun-fish) with a short tail.

Only one of the sun-fishes is common in the vicinity of Europe and in the Mediterranean, namely, the short sun-fish (*Mola rotunda*), which attains a length of from 8 ft. to 10 ft. or more, and a weight of more than a ton. The oblong sun-fish (Ranzania) has occasionally been found near the shores of Europe, but *Mola lanceolata* has never yet been met with in these waters, and only once, by Prince Albert of Monaco, in the open sea near the Azores.

To judge from the number of adult specimens known, *Mola rotunda* must, therefore, be by far the commonest species, *Ranzania truncata* less common, and *Mola lanceolata* very rare.

The *Dana* expedition (1920–22), however, reveals an entirely different state of things as regards frequency of occurrence, so far as the early developmental stages are concerned.

On the first *Dana* expedition, in 1920, we found, in the Sargasso Sea, eggs and early stages in great numbers, chiefly those of Ranzania, but also many of *Mola lanceolata*.

These stages, described in the issue of NATURE above mentioned, were found in such abundance in the Sargasso Sea that there can be no doubt but that this sea is a very important breeding-ground for both species. Of *Mola rotunda*, on the other hand, we found not a single specimen in the early stages. Here, then, we encountered a phenomenon not unknown to the marine biologist, to wit, the fact that species which are "rare" in the adult forms may be "common" in the larval stages, and vice versa.

On the second *Dana* expedition, 1921–22, we found the same thing again; here, however, in addition to many early stages of Ranzania and of *Mola lanceolata*, we also obtained a single specimen of *Mola rotunda*, 5 mm. long. It is possible that there may be one or two more specimens in the material, but up to now this is the only known early representative of *Mola rotunda*, the commonest or best known of all sun-fishes, and is therefore of no slight interest.

It is shown in the accompanying illustration, Fig. 1, and together with a specimen of *Mola lanceolata* of equal size, in Fig. 2. The great difference in appearance of the two is noticeable at a glance, without going into details. *Mola rotunda*, for example, lacks the enormous development of some of those spines which are peculiar to the early stages of sun-fishes, while on the other hand, the so-called eye-spines are rather more strongly developed in *Mola rotunda* than in *Mola lanceolata*.

Another feature of interest should also be noted. The larvæ of *Mola lanceolata* were, as mentioned, common in the Sargasso Sea, whereas of *Mola rotunda*, not a single specimen was found here; despite the fact that the *Dana* expeditions fished very intensively in these waters.

The only known early stage of *Mola rotunda* was found in a region west of the Sargasso Sea, where the expedition worked to a very slight extent compared with our operations in the Sargasso Sea, namely, at St. 1238 (26° 13′ N., 78° 48′ W.), about 20 miles south of Grand Bahama Island. *Mola lanceolata*, on the other hand, was not found here, but was taken at the subsequent stations east of Bahama (*e.g.* St. 1240 at 25° 35′ N., 74° 45′ W.).

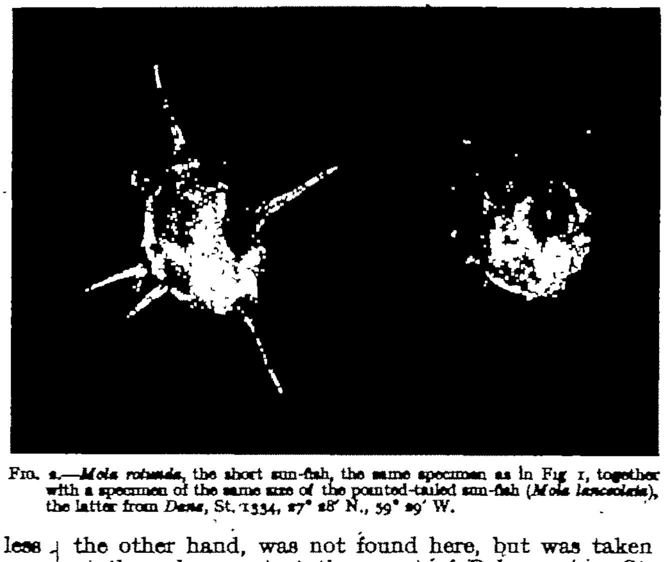

FIG. 2.—*Mola rotunda*, the short sun-fish, the same specimen as in Fig. 1, together with a specimen of the same size of the pointed-tailed sun-fish (*Mola lanceolata*), the latter from *Dana*, St. 1334, 27° 28′ N., 59° 29′ W.

So long as only a single specimen is known, it is of course impossible to say anything definite, but the question naturally suggests itself: May not the frequency of *Mola rotunda* as an adult form, in contrast to *Mola lanceolata*, on the shores of Europe, be primarily due to this very fact, that its spawning grounds lie farther west than the latter, rarer species, so that its larvæ would have more chance of being carried passively by the Gulf Stream and the Atlantic Current over to the European side ?

I have to thank Mr. Å. V. Tåning for undertaking the difficult task of photographing the specimens shown, and also for valuable assistance in other ways.

JOHS. SCHMIDT.

Carlsberg Laboratory,
December 2.

The Energy Levels of the Nitrogen Molecule.

IN a paper before the American Physical Society (*Phys. Rev.*, 23, 294, Feb. 1924) and in a letter to NATURE (Nov. 1, 1924, vol. 114, p. 642), I gave a set of electronic energy levels for the neutral nitrogen molecule, based on an analysis of its band spectra. These levels were designated *X*, *A*, *B*, *C*, and *D*, where *X* denotes the stable state of the molecule. The interval *X* to *A* was suggested as 65,000 (= 8·0 volts), the band system corresponding to this transition being as yet unknown. Dr. Sponer (*Zeitsch. f. Phys.*, 34, 622, 1925), by measuring the excitation potentials of various groups of nitrogen bands, has now obtained results in exact agreement with this diagram. The *X* to *A* interval comes out as 7·9 volts.

Duncan (*Astrophysical Jour.*, 62, 145, 1925) also has measured excitation potentials in molecular nitrogen. In discussing the theory he has stated that the 0–0 band of the second group (λ3371) should be excited at a potential higher than the 0–0 band of the first group (λ9108) by 2·3 volts. This, however, is incorrect. The difference should be 3·66 volts, corresponding to the frequency of the 0–0 band of the second group. However, the bands of the first group which he *actually observed* should be excited at about 2·0 volts less potential than the 0–0 band of the second group, in agreement with his actual results (10 and 12 volts respectively). With this correction, and with the assumption that all of his measured potentials are about 1·3 volts too low, there is agreement between his results and those of Dr. Sponer, as well as with my theoretical diagram. The only measurement by Duncan in error by more than his stated probable error is that for the weak fourth positive group.

As a result of my analysis of the nitrogen levels, I further stated that the carrier of the characteristic afterglow bands of active nitrogen was a neutral nitrogen molecule with 11·5 volts of energy (9·3 volts electronic and 2·2 volts vibrational) in excess of the stable state. The afterglow phenomenon was noticed by E. P. Lewis and the chemical activity associated with the afterglow was discovered some ten years later by Lord Rayleigh, who gave the name "active nitrogen" (see NATURE, Nov. 15, 1924, vol. 114, p. 717). As has been customary, I identified the carriers of the afterglow bands with the entity responsible for this chemical activity, and hence was forced to postulate that this molecule with 11·5 volts excess energy was in a metastable condition. Because this condition corresponded to the high vibrational quantum number eleven, there are grave theoretical objections to such an assumption, and Dr. Sponer now assumes that "active nitrogen" is atomic nitrogen. The recent work of R. W. Wood, Bonhoeffer, and others, on atomic hydrogen, and of Franck and his co-workers on "collisions of the second class," now make such an assumption not only possible, but plausible, even though the afterglow (a secondary effect of the *association* of atomic nitrogen) has been obtained with a duration of more than fifteen minutes (R. Rudy, *American Physical Society*, Nov. 1925). The full argument is given in her paper, to which reference has just been made, and leads directly to the conclusion that the 11·5 volts of excess energy of the carriers of the afterglow bands measures accurately the heat of dissociation of nitrogen.

After the emission of the afterglow bands, the excited nitrogen molecule is in state *A* and has 9·4 to 8·9 volts of energy. The bands corresponding to the transition *A* to *X* should lie in a spectral region where Prof. Hopfield and I later found a system of bands (NATURE, July 4, 1925, vol 116, p. 15), but this system gave progressions which, on the basis of the data then available, agreed with no other known progressions of nitrogen or of any other molecule. Using data which have recently become available, Dr. Sponer has now been able to classify this system, and her results are given in the accompanying letter.

RAYMOND T. BIRGE.

University of California,
December 5.

The Energy Levels of the Nitric Oxide Molecule.

IN a recent letter to NATURE (July 4, 1925, vol. 116, p. 15) R. T. Birge and J. J. Hopfield record the observation of a system of emission bands in nitrogen in the region of λ1854–λ1250. They found a formula for these bands that did not fit into the known level-scheme of nitrogen. This was a peculiar fact because the bands arising from the normal state of the N_2 molecule are to be expected in this region. The apparent discrepancy can now be explained by the discovery that these bands do not belong to the N_2 but to the NO molecule. This is quite possible, as the nitrogen used was not completely free from oxygen.

I am much indebted to Prof. J. J. Hopfield for giving me the opportunity to see the manuscript of an investigation by S. W. Leifson, on absorption spectra of different gases and vapours in the Schumann region (*Astrophysical Journal*, in press). By comparing the frequency differences of the NO bands of Leifson with those in the above-mentioned band system of Birge and Hopfield, I find that both systems have a common state. The final state of the absorption NO bands of Leifson is also the final state of the emission bands of Birge and Hopfield. Moreover, with the aid of new wave-length measurements of certain bands of the third positive group of nitrogen, kindly made for me by Prof. Hopfield from his plates, I find that the absorption bands of Leifson are merely the 0–0, 0–1, 0–2, etc., bands of the third positive group. Leifson's plates contain also the Birge and Hopfield bands.

Hence we have conclusive evidence that the third positive group belongs to NO, as has usually been assumed, and that its initial state in absorption is the normal state of the NO molecule, as Mulliken (NATURE, Sept. 6, 1924, vol. 114, p. 349) and Birge (*ibid.*, Nov. 1, 1924, vol. 114, p. 642) had suggested. The excitation potentials of the levels of the NO molecule can be given from these considerations as 5·44 and 5·44 + 8·52 = 13·96 volts; that is, 5·44 volts for the excitation of the 0–0 band (λ2269) of the third positive group, and 13·96 volts for the excitation of the 0–0 band (λ1450) of the Birge and Hopfield bands. From this it follows that the ionisation potential of the NO molecule must be greater than 14 volts.

I am glad to have had the opportunity to discuss these matters with Prof. R. T. Birge, and wish to thank him for his friendly co-operation.

HERTHA SPONER.

The Study of Taxonomic Zoology.

THE proper study of any aspect of zoology involves the consideration of the following facts: (1) the external world, in contradistinction to the organism, is undergoing constant and ceaseless change; (2) the organism itself is similarly subjected to change; (3) the organism and its environment are in a constant state of reaction. The physical sciences aim at a correct understanding of what is happening in matter in its innumerable aspects and the reality underlying these changes. The biologist seeks to elucidate the phenomena connected with the organism, but his study is never thorough unless an attempt is made to correlate the relation of the changing organism to the external world. It is not possible to explain correctly the form, shape or function of a particular organ, or the behaviour of a particular organism and its relationships to other organisms, without taking into account the third consideration mentioned above, in other words, that every organism is trying to fit itself to live in its particular surroundings. This effort on the part of the organism is, to a large extent, conditioning its structure, its behaviour and its life-processes.

The primary object of taxonomy, or the systematic study of a group of animals, is to discover their relationships and to facilitate the advancement of this object by assigning to groups of individual kinds of organisms generic and specific names, grouped into more comprehensive sections such as families, orders, etc., according to the method instituted by Linnæus. Such names when first proposed must be accompanied by a description of the animal to which it applies, in which, so far as is possible, its relationships must be emphasised. It is assumed that the manifestation of relationship is resemblance, and in order to establish the affinities of one species with another they must be generally similar in structure, development, behaviour and habits. Practically, however, complete information about an organism is very often not available, and the systematist has therefore to make the best of the data at his disposal (which at present is for the most part morphological) in expressing an opinion on the affinities of the organisms he has studied. In doing so, he assumes further that the individuals showing these resemblances will breed true, and that no two such groups regarded as different will interbreed in Nature in ordinary circumstances. To this conception of closely allied, but different, groups of individuals the name "species" is given. In considering this concept of a species, it must be remembered that a general statement or "law" is true only within certain limits, and that the same organism will behave differently when these limits are exceeded and will acquire new properties and characteristics.

Resemblance presupposes differentiation. The recognition of resemblance follows from the true estimation of the value of differences in characters, and for the purpose of establishing relationships the proper estimation of this value is very important. The value of characters varies according to the group of animals dealt with, what is considered sufficient for establishing a species in one group being considered insufficient in another. The appreciation of this depends on the systematist's experience and on the extent to which data are available. In some groups (*e.g.* trypanosomes) where anatomical data afford no clue for the differentiation of species, the physiological reactions they produce are relied on for specific determination. The variation of the value of characters is a fact that the taxonomist must always bear in mind.

Zoology has from its beginning been an observational science, and even now its purely observational and descriptive aspects have by no means been exhausted. Important conclusions have been derived from observation alone. It is possible to generalise from the observation of a large number of apparent facts, but such generalisations cannot be more than tentative hypotheses, their probable accuracy being proportional to the number of observed facts. It is here that the value of experiment in increasing the proportional accuracy of a hypothesis must be recognised. The observation of an orderly sequence of events in Nature may be considered by some sufficient for a generalisation, but it seems to me that the introduction of a disturbing element in a given series of events must result in giving us a more complete insight into the nature of things. To recognise relationship by the interpretation of structure, physiological reactions and habits of animals, taxonomy would be in a better position if the opinions of the museum zoologist were tested by experiments in development, in breeding, in ecology, and in the habits of the organism. The need for experiment cannot be too strongly emphasised.

Yesterday our astronomy was geocentric; to-day our biology is anthropocentric. Animated Nature has been, and is still, studied and interpreted through human emotions and prejudices, and it is this inability to assume a detached state of mind in studying Nature that is responsible for the lack (as compared with the mathematical sciences) of rigid thinking in biology. It must, however, be admitted that it is easier to maintain an impartial attitude when considering inanimate Nature than is possible in the study of organisms more or less similar to ourselves. We are too apt to regard man as the highest "created" being, superior to all animals, and this view colours most of our observations, especially those of the purely field-naturalist. We have no evidence for supposing that the fair face of Nature exists for the sole pleasure and benefit of man, and until we cultivate the attitude of regarding ourselves as but one kind of organism in the phenomena of life, we cannot hope for careful observations free from personal likes and dislikes. I stress the fallacy of egoism in zoology largely because the systematist has often to depend on the observations of the field-naturalist in his study of the relationships of the animals with which he deals. It is not given to every systematist to be an ecologist or an experimentalist as well, and it is only by the co-operation of untrammelled minds that we can hope for much future progress in biology.

S. MAULIK.

Spermatogenesis in Spiders and the Chromosome Hypothesis of Heredity.

REFERRING to several letters which have appeared in NATURE (September 12, October 3, October 17) on the spermatogenesis of spiders, I have now examined the testes of a number of South African spiders, and it is found that the chromatin behaviour and the absolute dimensions of the spermatogonia and spermatocytes may differ extraordinarily in different species, even when these species are not far removed systematically from one another.

In some of the species there is a variable amount of more or less typical spermatogenesis with the formation of spermatocytes by mitosis, but in addition, in all the species investigated by me, there is an extensive production of apparently functional spermatozoa by some form of amitosis, and in certain species typical spermatogenesis appears to be almost entirely absent.

In the case of *Amaurobius sp*, recently examined by Miss S. D. King, it may very well be that in that species there is a considerable amount of mitosis in the formation of the spermatocytes, but I accept with much less confidence the assumption that the spermatogonia divide only by mitosis. In the thousands of sections of testes which I have examined I have met with very few examples of the karyokinetic division of spermatogonia.

The conclusions which the present observations seem to suggest are:

(1) In spiders it is usual for the spermatogonia to multiply by amitosis.

(2) The spermatocytes arise in a variety of ways, and in certain species the typical mitotic process has been almost entirely superseded by some form of abbreviated or simplified spermatogenesis, and a single spermatogonium may give rise to less than 4 or considerably more than 4 spermatozoa.

In species in which typical sperm-formation is greatly reduced, or practically absent altogether, there may, nevertheless, occur among the spermatocytes a certain amount of incompleted or erratic karyokinesis, but this is sporadic and is not an essential part of the process of sperm-production in those particular spiders. For example, a symmetrical spindle may be formed, but then perhaps no dyaster arises, and afterwards the chromosomes break down and the cell forms spermatozoa in some atypical manner.

(3) In the testes of some species, spermatozoa of two sizes can be distinguished. These may originate in very distinct ways, and the two kinds may be approximately equal in number. There is no evidence that the smaller spermatozoa are degenerate forms. In certain species there seems to be a certain rhythm in the development of the two kinds.

(4) Owing to the fact that in some species the spermatozoa arise almost exclusively by an atypical method, it is not possible to suppose that such spermatozoa are degenerate and incapable of fertilising the ovum.

(5) The spermatozoa may undergo great reduction in size and modification in shape in the epididymis or convoluted tube which connects the testis with the vesicula seminalis. In one species of Attus (?), for example, the spermatozoa in the epididymis become converted into short, stout and perfectly straight rods, and in another species of the same or allied genus they assume a very characteristic and symmetrical fusiform shape. The distinction between large and small kinds of spermatozoa, which may be well-marked in the testis itself, becomes less obvious in the mass of ripe spermatozoa contained in the epididymis and vesicula seminalis.

It is thus clear that there is a remarkable and very interesting diversity in the character of the ripe spermatozoa of spiders.

(6) The multiplication of the spermatogonia by amitosis and the great differences which occur in the behaviour of the chromatin in the origin of the spermatocytes of spiders renders it exceedingly difficult, or impossible, to understand how the complicated factorial architecture, postulated by the chromosome hypothesis of heredity, could be transmitted in any material sense from one generation to another.

In this connexion it may be stated that in a paper about to be published in the *Annals of the Natal Museum*, I am describing the extensive occurrence of amitosis in the early development of the body-tissues and ovary of the embryo of *Palystes natalius*. This amitosis takes place both by binary fission and by fragmentation of the nucleus, and as these cells form a constituent part of actively growing tissues, it is extremely improbable that their offspring should be incapable of dividing by typical karyokinesis.

With such facts as these before us, it is indeed problematical how any definite arrangement of material genes could be maintained in the chromosomes, either in the growth of the tissues or in hereditary transmission.

As a good corrective to the view of the all-sufficiency of chromosomes, and to the tendency to substitute cellular structure in the place of the directive vital activity of the organism, I would recommend a close study of spider spermatogenesis.

ERNEST WARREN.

Measurement of Radiation Intensities by Photographic Methods.

THE use of the photographic plate for the comparison of radiation intensities is becoming of greater importance every year. There are two essentially different methods available, and since considerable work is being done in connexion with the method which appears to us least sound, it does not seem out of place to record briefly the general principles involved, with the view of indicating which, in the opinion of the staff of the British Photographic Research Association, is to be preferred.

The first method, and one which has been used very considerably in the past, depends on the characteristics of the particular kind of plate used in making the measurements, that is, it involves the preliminary calibration of the plate. By this is meant a determination of the blackening or photographic density which results from various exposures to known intensities of the same quality of radiation as is to be measured, that is, an accurate "characteristic curve" of the emulsion must be determined. From such a curve the intensity corresponding to any given density is read off. If the actual times of exposure employed when measurements are being made are not the same as those used when the particular kind of plate was calibrated originally, then the problem becomes very complicated owing to the failure of the Bunsen-Roscoe law, which states that a given density is produced by a given value of the product of intensity and time, and is independent of the actual values of each factor. To get over this difficulty the preliminary calibration has also to include a determination of the value of the so-called Schwarzschild's Constant, that is, the value of p in the expression $D=I\,.\,t^p$, connecting the density with the intensity and time of exposure. Still further complications arise, since p is not usually a constant, but varies with the intensity. When in addition one realises that these characteristics must be determined for every different wave-length which it is desired to measure, some idea is obtained of the immense amount of preliminary work involved. Further, it is possible for a new batch of plates, presumably of the same kind, to be sufficiently different to upset the results completely.

The main feature of the second method is that the plate is used solely as a detector of equal intensities of the same kind of radiation, that is, the only assumption made is that on adjacent portions of a plate, radiation of the *same* intensity, of the *same* quality, acting for the *same* time, will produce the *same* effect when the plate is developed. To compare the intensities of two beams of the same wave-length by methods based on this principle, the intensity of the stronger beam is cut down until the effect it produces on the plate is the same as that of the weaker for the same time of exposure, etc. For example, if this is achieved when the stronger beam has to be cut down to one-tenth (by a method which does not involve an intermittency effect), then it follows at once that the ratio of the original intensity of the stronger to that of the weaker is 10 : 1. Obviously the great advantage of this method is that it is independent of the kind of plate used, so that all the arduous work of calibration is avoided, and one depends for accuracy, so far as the photographic plate is concerned, only on the constancy of emulsion characteristics over a small portion of any single plate, a fact which must make for considerably greater accuracy. This method, of course, involves the cutting down of the intensity of the stronger beam in a known manner at all wavelengths, preferably by a "neutral" absorbing screen. No difficulty now seems to exist in regard to this, since successful methods have been used by various workers.

As has been stated, this note is prompted by the amount of work which is still being done on the calibration of certain types of commercial plates, presumably with the view of using them for the first method described above. In our opinion the second method is vastly to be preferred.

Valence Theories and the Magnetic Properties of Complex Salts.

I HAVE followed with considerable interest the discussion which has been recently carried on in NATURE by Messrs. Jackson, Welo and Baudisch on the magnetic properties of the complex compounds of iron and other elements belonging to the first transition group. Two papers on this subject have recently been contributed by me, the first of which was sent in June to the *Philosophical Magazine* and deals with those complex compounds, the magnetic properties of which have been studied by Rosenbohm and Oxley. I have defined with Sidgwick the "effective atomic number Z'" of the co-ordinating atom in any complex compound, as the sum total of all the electrons contained in the former plus the number of electronic orbits which this atom shares with the neighbouring atoms and groups in the co-ordination compound. It can be shown that $Z' = N - E + 2P$, where N = atomic number of the co-ordinating atom, E = its primary valency in the given compound and $P = 4$, 6, etc., according as the complex compound is either fourfold, sixfold, etc.; *e.g.* in the ferrous compound $K_4[Fe(CN)_6] + 3H_2O$, $Z' = 26 - 2 + 2 \times 6 = 36$; while in the case of the fourfold compound of copper $[Cu(NH_3)_4](NO_3)_2$, $Z' = 29 - 2 + 2 \times 4 = 35$. These numbers can be independently calculated by the rule which has been given by Sidgwick.

In the above-mentioned paper I have shown that if Z represents the atomic number of the inert gas which terminates any transition group of elements, *e.g.* in the case of the iron group the inert gas is krypton with $Z = 36$, then all those co-ordination compounds, in which $Z' = Z$, are diamagnetic, while the others are paramagnetic. This result agrees with that given by Messrs. Baudisch and Welo in their letter (NATURE, October 24, p. 606). In a second paper, which was written immediately after the publication of Mr. Welo's letter in NATURE (September 5, p. 359) and has been sent to the *Zeitsch. f. Physik* for publication, I have shown that the number of Bohr's magnetons contained in any co-ordination compound of the first transition group of elements, the magnetic properties of which have so far been studied, is given by $Z - Z'$. The following table shows how the values of the magneton numbers, calculated according to the above rule, agree with the experimentally determined ones:

Compound.	Exp. Magneton No.		Eff. At. No.		
	Weiss's	Bohr's	Z'.	Z.	$Z-Z'$.
$[Cr(NH_3)_6]I_3$	19	3 (19·2)	33	36	3
$[Fe(CN)_6]K_4 + 3H_2O$	Dia	Dia	36	36	0
$[Fe(CN)_6]K_3$	10	1 (8·6)	35	36	1
$[Co(NH_3)_6]Cl_3$	Dia	Dia	36	36	0
$[Ni(NH_3)_4]SO_4$	13	2 (14·1)	34	36	2
$[Ni(NH_3)_6]SO_4$	16	2·5 (16·7)	38	36	2
$[Cu(NH_3)_4](NO_3)_2$	9	1 (8·6)	35	36	1

I have placed in brackets next to the Bohr's magneton numbers, the equivalent number of Weiss's magnetons, calculated on the assumption that the co-ordinating atom is in the "S" state. It will be seen that there is good agreement between the calculated and experimentally determined number of Bohr's magnetons contained in this class of co-ordination compounds. It remains to be seen whether further investigations will show that modifications are necessary. Incidentally, the above rule affords further evidence of the reality of Bohr's magnetons.

Mendelian Genes and Rates of Development.

PROF. J. S. HUXLEY and Mr. E. B. Ford have directed attention in NATURE of December 12 to the developmental mechanism connecting the Mendelian gene and the visible character. A field for an attempt to learn something about this mechanism was suggested to me some little time ago, by Prof. W. Garstang. Many problems of genetics, he pointed out, are connected with the hair and its colour in mammals, and therefore any process that is concerned in the distribution, development, or succession of hairs should be studied as minutely as possible.

My work has so far been confined to the mouse (*Mus musculus*). A study of the coat was first carried out as a piece of pure morphology in order to provide the necessary basis for the examination of the effects of known genes. A paper on this is shortly to appear. It will be enough to mention the following points. The hairs of the same region of the coat are of several types; the growth of a hair takes place entirely at the basal end, any individual hair taking about four weeks at the most to become fully formed; and, broadly speaking, all the hairs growing at the same time in any small area of the skin pass through much the same stage of development together.

At present I am occupied with the colour pattern of the wild mouse. Agouti, as is well known, is a simple dominant to black. Agouti differs from black in that some hairs have a sub-apical pale band that is in most cases yellow, though some are black throughout. As Prof. Garstang himself anticipated, there has proved to be a simple key to the agouti pattern. On the back of the mouse the presence or absence of the light band can be correlated with hair-type; and in types possessing the band its length and shade can be correlated with the size of the whole hair or of some part of the hair. In every case there is some dark pigment at the apical end, the part of the hair first formed. Within a short distance in yellow-banded hairs the dark pigment gives place partly or completely to yellow, and then proximally black gradually replaces yellow, and no yellow pigment is formed in the rest of the hair. In some cases no yellow pigment can be seen in the light band, but the concentration of the dark pigment is less than in the adjacent regions. In attempting to interpret the facts just outlined, various details of hair development must eventually be taken into consideration. It may be mentioned that in the follicles of two adjacent hairs of the same type, in one the yellow band may be in process of formation after the banded portion of its neighbour has been fully formed and the production of black pigment resumed.

In the light of the discussion of the agouti pattern in rodents by Sewall Wright (*Carnegie Inst., Wash.*, 241, 1916, and *Jour. Heredity*, 8, 1917), and of Onslow's work cited by Huxley and Ford, we may conclude that in the region of the light band the production of black pigment is partly or completely inhibited, while, of course, the colour of any part of a hair depends upon the rate at which different substances are produced.

Some few months ago I was able to discuss this work with Prof. Huxley, who suggested subjecting the animals to different conditions and observing the effect upon the agouti pattern. It also occurs to one that comparative studies should be made on the series of multiple allelomorphs, yellow, white-bellied agouti, agouti, and black. It has not yet been possible to undertake these investigations. They are mentioned as indicating further the possible usefulness of this line of inquiry.

F. W. DRY.

The University, Leeds, December 15.

The Leaping Salmon.

THE word salmon, in late Latin *Salmo* (for the fish was unknown to the Greeks), comes from *salio*, to leap; for all salmon run up the streams from the sea in the fall to cast their eggs in clear cold waters, for them to hatch as the waters grow cold. In this regard they are unlike most other fishes (birds and reptiles as well) whose eggs hatch as the weather becomes milder.

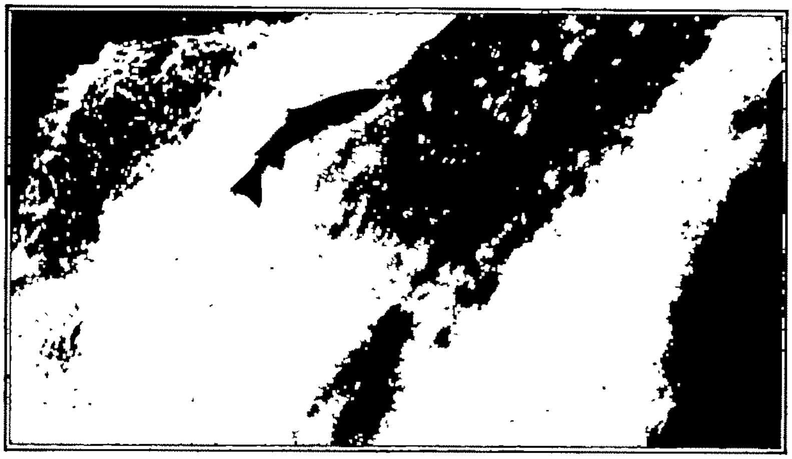

FIG. 1.—King salmon leaping the Punch Bowl Falls, Cascade Range, Oregon, 30 ft. high.

When salmon encounter a waterfall, they leap over it if they can. In a broken cascade they may worm their way through and around. This is true in tributaries of the Atlantic and Pacific alike. But while there is but one kind of salmon in the Atlantic, and that one much like a big trout, there are five kinds on our Pacific coast, and those quite different from the Atlantic salmon as well as from one another. These are the king salmon, known also as Chinook or Quinnat; the red salmon of Alaska, known as Blueback and as Sockeye (*Sukkegh*); the silver salmon or Coho; the calico salmon or Chum; and the hunchback salmon. All these agree in developing but one set of eggs, dying after once spawning. The noble salmon, king and red, mostly spawn the fourth year; the smaller hunchback the second year, the others at three or four. A few individuals delay the operation, growing to a correspondingly larger size. The red salmon, unlike all others of its kind, enters only streams that have a lake in their course. They spawn in streams at the head of the lake, and in it the young fishes mostly spend their first year. The other species are less particular, but some of them will ascend a stream for fifteen hundred miles (to Lake Laberge in the Yukon country, for example) before the suitable stream is found.

All salmon will leap over a waterfall where it is possible or necessary. I present here the finest picture of a leaping salmon I have ever seen (Fig. 1). An artist has to be keenly on the watch to take a picture like this. It represents a king salmon of about twenty-five pounds springing over the Punch Bowl Falls in the Cascade Range, Oregon, the height being about thirty feet. For this picture I am indebted to a former student, Helen Gibson (now Mrs. Rockhold), resident in Oakland, and for the purpose of placing this charming picture on record, I write this little sketch.

DAVID STARR JORDAN.

Detonating Meteors.

THE descriptions of a brilliant meteoric fireball in NATURE of November 28, p. 795, and in two letters dated November 17 and November 28 from Mr. W. F. Denning to the *Times*, give details of the attendant acoustical phenomena which are perhaps worth examination.

It appears that at least 25 miles above Hounslow detonations occurred, and these not only originated sound at that great height, but were also heard loudly at Caterham after passing down through at least 30 miles of the atmosphere.

The loud and thunder-like sounds would appear to be the chief, if not the only, reason for supposing a detonation to take place. Mr. Denning has confirmed in a letter to me that the accepted explanation of the origin of the sound is that there is a detonation resulting from the great heat due to the swift passage of the meteor against the resistance of the air.

The sounds need not necessarily arise from a detonation or explosion, however, for a body moving through the air with a velocity greater than that of sound will on that account give rise to an intense and sudden sound, which in the now familiar case of a high velocity shell or bullet was commonly supposed to originate from the explosion of the propellent charge. The "shell wave" or "onde de choc" to which the loud crack is due is readily understood if Huyghen's principle is applied to this case, supposing the body to be causing disturbances in the air all along its path in the same way as a slowly moving object causes a rushing or tearing sound. Prof. Boys has actually photographed the "onde de choc" of a bullet in flight (reproduced in Barton's "Text-Book on Sound," p. 82), but we have a familiar analogy in two dimensions in the bow wave of a ship.

It is difficult to estimate the speed of sound at a height of 25 miles, but the result of an experiment by S. R. Cook (*Phys. Rev.*, 23, pp. 212-237, September 1906), on the speed of sound in air at liquid air temperatures, might be taken as a limiting case. At 91° A. he found the speed to be 181 metres per second. The speed computed for the fireball of November 15 was about 17 miles per second. At 91° A. this would be about 150 times the speed of sound, and at normal ground temperatures of, say, 283° A. it would be still 80 times the speed of sound. For these high speeds the "onde de choc" would be a conical wave of such a narrow angle that the wave front could be regarded as parallel to the line of flight. This fact might serve to discriminate between sounds due to an explosion at a point in the path of the meteor and that due to its "onde de choc."

In the case of thunder to which the sound of the meteor has been likened, the originating lightning flash is practically instantaneous and usually takes a very irregular path. The sound wave begins with a front shaped like the flash, and this, even more than reflection, probably accounts for the prolonged sound of rising and falling intensity to a distant observer. The flight of a meteor is more regular, and its sound would be expected to be more uniform in intensity than thunder. It may, however, be complicated by the separate "ondes de choc" of fragments thrown off in the course of its flight.

Einstein Shift and Doppler Shift.

IN answer to Sir Oliver Lodge's question (NATURE, December 26, p. 938), it depends on our point of view whether the Einstein shift is considered to be imposed on the light at its origin or in course of transit to us. We cannot state the frequency of the ether vibrations without presupposing a system of time-reckoning, and in the non-Euclidean region round the gravitating star the ordinary conventions of time-reckoning have broken down. There is a particular system of time-reckoning (t) commonly used in relativity investigations; but it must be understood that no merit is claimed for this system except that it renders certain calculations easier. In this reckoning the Einstein shift occurs at the origin of the light, and is carried to us by the light without change. But if we pay attention rather to the proper-time (s), which gives us an absolute point of view, atomic vibrations have the same period s wherever they are situated; and the Einstein shift is imprinted on the light as it travels through the non-Euclidean region into the comparatively flat region of space-time where we observe it.

The answer to any problem of observation must, of course, be the same whichever point of view we take. The companion of Sirius will not produce the shift in light reflected by it from another source, because alternatively (1) no change of period t occurs, or (2) the change of period s during the approach is neutralised during the recession. I should add, however, that the so-called reflection of the light of one star by another (often conspicuous in eclipsing variables) is really an absorption followed by re-emission; and this kind of "reflected" light would suffer the Einstein shift.

Genes and Linkage Groups in Genetics.

IN the flatfishes "mutations" are not uncommon; albinos, piebalds, etc., reversed examples (sinistral individuals of dextral species and dextral individuals of sinistral species), and ambicolorate fish. There are many degrees of ambicoloration, from specimens with a small coloured patch or a few scattered spots on the blind side to others in which the whole blind side is coloured like the eyed side. When ambicoloration is complete, or nearly so, it appears always to be associated with other variations; the migration of the eye is delayed, so that it gets in the way of the dorsal fin as it is growing forward on the head, the scales of the blind side resemble those of the eyed side in structure, the asymmetry of the paired fins is less marked. It is clear that the one thing that holds these variations together is that they are variations towards symmetry, and it is interesting to note that the head, which is the most asymmetrical part of the fish, is the last to be affected; thus it often happens that the whole blind side is coloured except a patch in the orbital region, and that the scales of the blind side are as rough as those of the eyed side except on the head.

The basis of this linkage group—ambicoloration, monomorphic scales, delayed migration of eye—is a tendency towards symmetry. These facts seem to be capable of an interpretation not very different from that given by Prof. MacBride in his letter in NATURE of December 26, p. 938.

The Palæolithic Drawing of a Horse from Sherborne, Dorset.

IN the third edition of his "Ancient Hunters," p. 536, Prof. W. J. Sollas states that the drawing of a head of a horse on bone from Sherborne, which I described in 1914 as an example of Palæolithic art, "is a forgery perpetrated by some schoolboys." I read this statement with surprise, because the bone is in a semi-fossilised condition, and I think all who study the specimen will agree that the drawing must have been made when it was fresh. When it was exhibited to the Geological Society, indeed, it was generally accepted as of Palæolithic age. Through the kindness of Mr. Nowell Smith, headmaster, and Mr. R. Elliot Steel, formerly science master of Sherborne School, I have therefore communicated with Mr. Arnaldo Cortesi, the survivor of the two schoolboys who discovered the bone. He writes, "I confirm the genuineness of the find," and remarks that at the age of fifteen years he was too ignorant of the subject to take part in any such "trick" as Prof. Sollas suggests.

I may add that in the autumn of 1923, with the kind permission of Major Wingfield Digby, Mr. Elliot Steel and I examined one of the fissures in the quarry whence the bone is supposed to have been obtained, but we had no success. The teeth of mammoth and rhinoceros from the lower part of the same valley, now in the Sherborne School Museum, are still the only other Pleistocene remains from the neighbourhood.

Aptitude and Achievement.[1]

By Prof. J. McKEEN CATTELL.

THERE was published in 1890 in *Mind* an article entitled "Mental Tests and Measurements," and in 1896 in the *Psychological Review*, established in the meanwhile in co-operation with Prof. Baldwin, an article entitled "Physical and Mental Measurements of the Students of Columbia University." This was the first series of tests used with a large number of individuals, and it still remains the most extensive undertaking of this character. The students were tested at the beginning of the freshman and the end of the senior year, the women of Barnard College as well as the men of Columbia College.

About an hour was given to the examination of each student, and some thirty measurements were made, ranging from height, weight, and lung capacity, through keenness of sight, discrimination of pitch and reaction time, to memory, imagery, and association. In addition, some forty records and observations were made, ranging from colour of eyes and hair to an estimation of intelligence and straightforwardness. Further, the student at home filled in a blank answering some eighty questions, ranging from the ages and, if deceased, cause of death of his grandparents, to what profession or business he proposed to follow and in what calling he would prefer to succeed if he had his choice. Other information was also available, including class standing in different subjects, success in athletics, and social interests. It is possible to follow the careers of alumni in after life and to measure their children when they in turn come to college at about the same age. In addition to the Columbia students, these tests were made on members of the American Association for the Advancement of Science at three annual meetings, measurements having been obtained of men so distinguished as Simon Newcomb and William James. At the St. Louis Exposition of 1904 a laboratory was set up and tests were made by Prof. Woodworth and Dr. Bruner, both on the visitors and on the racial groups that were represented.

In working over the tests, Dr. Wissler used for the first time in psychology the methods of correlation developed by Francis Galton and Prof. Pearson. The correlations among the grades in different studies were significant and have been the basis of many subsequent studies. The lack of correlations among the measurements was at the time disappointing. It is due in part to the attenuation from measurements that are only accurate when deduced from averages, in part to a real lack of correlation in different traits. For example, a student who is accurate may be as likely to be quick or slow as one who is inaccurate. There is no correlation, but one-fourth of all students will be above the median, one in a hundred in the first tenth, in both accuracy and quickness, and will have a great advantage. The correlations—due to the circumstance that the same abilities and training are involved—discovered among complicated performances, such as class work and intelligence tests, have led to their cultivation and to the neglect of the simpler measurements. The cultivation is desirable, the neglect unfortunate. It is of interest to any one to know where he stands among others in these traits and determinations; some of them, such as colour-blindness or acuity of hearing, which can be measured in a couple of minutes, may be of real use. It is also the scientific method to be followed in analysing the more complicated processes, such as those going under a term so ambiguous as general intelligence.

Estimates of character and of other psychological traits are difficult and untrustworthy. No correlation has been found in the Columbia laboratory between size or shape of head and ability of any sort. There is no known relation between complexion, forehead, nose, chin, or other features and psychological traits. The reading of character by physiognomy or graphology is the occupation of charlatans. It is difficult or impossible to tell even the sex of the individual from the features of the face or from the handwriting. These are, of course, legitimate subjects of study. The full and side face have been photographed through a centimetre netting with a long focus lens, thus obtaining in a moment a large number of determinations, which are on the average as exact as can be got by direct measurement. The method can be used to advantage with children or savages, who do not like to be measured, and it is useful in recording and preserving a large number of determinations, some of which may prove to be of unexpected value. Photographs of the face were cut in parts to determine by what features we recognise the individual, and estimate the age, sex, etc. A study was also made in which individuals were judged first from a photograph, later after a five-minute interview, and then by individuals who knew them well.

It is possible to put judgments of character on a quantitative basis. In the earliest undertaking of this character, five instructors in Columbia University were graded on a percentile scale by twelve fellow-instructors and graduate students. Twenty-four traits or qualities were included, ranging from physical health to efficiency and leadership. There were used the psychological categories of intellect, emotion, and will, together with the quantitative differences to which they have a certain analogy, breadth, intensity and quickness. All these qualities are useful, but it is especially desirable that a scientific man should have broad intellect, an artist intense emotions, a soldier or statesman quick will. We can fancy that these are unit characters which are combined by chance in Mendelian fashion. The probable error in position in a centile order for different traits estimated by twelve observers was only 4 places, ranging from 3 to 5·2, and apart from constant errors there is thus a close agreement. The chances, for example, are even that a man ranked 51 for integrity, with a probable error of 5, is more honest and straightforward than 45 of a hundred of all scientific men and less so than 44. A man ranked 95 for courage with a probable error of 3 is to the best of our knowledge more courageous than 9400 of the 10,000 scientific men of the country, and the chances are even that this position is correct within 300 places. There was greater agreement on mental balance than on physical health; there was least agreement on cheerfulness, most on energy, perseverance, and efficiency.

---

[1] From the address, entitled "Some Psychological Experiments," of the retiring president of the American Association for the Advancement of Science, delivered at the Kansas City meeting on December 28, 1925.

There is a certain amount of validity in judgments of personal traits, character, and performance, and individual differences in the reliability of the judgments of those taking part in these experiments have been measured, showing a variation in competent observers covering a range of about two to one. It is an accepted truism that success in business and in other directions depends on the wise selection of associates and agents and on the ability to predict how others will act in given circumstances. When we learn to look upon our observations, recollections, beliefs, and judgments objectively, stating in numbers the probability of their correctness, there will be an extraordinary change in our attitude in religion, politics, business, and all the affairs of life.

Before the selection of a thousand students of Columbia University and a thousand American scientific men, a study was made of the thousand most eminent men of history, and this was the basis for the later studies by order of merit. From each of six French, German, English, and American biographical dictionaries or encyclopædias were selected about 2000 of those allowed the longer articles. From the some 6000 individuals so determined were taken those who appeared in at least three dictionaries, and from these were selected those given the greatest average space, the several dictionaries being reduced to a common standard. Thus was obtained not only the thousand men given most attention, but also the order in which they stand. The method further permitted the assignment of a probable error of position, which can be used as a measure of differences in eminence, and, if we assume the distribution of the probability curve, the differences between eminent men and average individuals.

Curves may be drawn showing the historical distribution of eminent men by nationality and by performance. After the Greco-Roman period and the so-called Dark Ages, there is a rise in numbers from the tenth century onwards, but with definite fluctuations in productivity. In the fifteenth century, Italy, England, France, and Germany had nearly the same number of eminent men. Italy was in the lead, but then falls, as does Germany, while England and France rise, their curves crossing through the centuries with nearly an equal number of distinguished men, England surpassing in the number of highest eminence. France reaches its culmination at the end of the eighteenth century. Germany rises rapidly from the second half of the seventeenth century, and the American curve then begins with much promise for the future.

An analysis of the kind of performance shows that France has excelled in war, science, and scholarship, England in politics, poetry, and philosophy, Italy in art. Of the eighteen great musicians, Germany has produced ten, Italy six. Of the fourteen great explorers, England has produced five, Spain four. Though text-books and treatises on history, at least until the most recent period, are mainly concerned with wars and politics, there have been fewer eminent sovereigns, soldiers, and statesmen than scientific men, philosophers, poets, artists, and the like. The rising curves for science, the falling curves for philosophy and the church, are significant. Soldiers have been surpassed in numbers by men of science, and the curves predict a gradual cessation of war and the predominance of science. Similar curves have been made for the percentage of the total population of different countries engaged in war through the centuries, and though the data were inadequate, they also point to the gradual elimination of war. But, of course, the projection of curves is a scientific method that must be used with the utmost caution. By similar methods a list of 1000 American scientific men who died prior to 1900 has been compiled, and the changing interests can be shown by curves. A quantitative study of history is a possibility of the future.

Data have been collected concerning some of the 1000 eminent men of history and a supplementary list of 10,000 has been used, with the view of placing information in regard to them on a statistical and quantitative basis, determining how they differ among themselves and from others, and the conditions favourable to performance. Our present information is from anecdotes and examples from which almost anything can be deduced. We do not even know whether history depends on its great men or whether these are by-products of economic and other forces. We do not know the extent to which their performance depends on heredity and on opportunity.

The distinctions hold not only for men of eminence, but also extend to differences adapting ordinary individuals to the work that they can do best. Thus three types of people, intergrading but often well defined, are those most satisfied and competent when dealing, respectively, with personal and emotional relations, whether the poet or the salesman; with material objects and definite situations, whether the military leader or the mechanic; and with abstractions, whether with the Deity or the atom, or simply with words and figures. In the transportation services, most of the employees have functions separated on the lines of these three types. The clerks, bookkeepers, and stenographers are concerned with words and figures; the conductors and pursers must remember faces, be obliging, ready to answer questions, interested in the affairs of the passengers; these traits are disqualifications for motormen and engineers, who should be concerned about objects and machines. By a rough natural selection those tend to become clerks, conductors, or engineers who are best suited for the work, but probably more than ten per cent. of the employees could be transferred with an average increase of more than ten per cent. in their efficiency; new employees could from the start be assigned to work for which they are best fitted. By the use of the psychological tests that we now have and by research to perfect these tests, the corporations concerned with transportation could effect a direct saving measured by tens of millions of dollars a year, indirectly of a comparable sum through the greater welfare and contentment of their employees.

In addition to the groups already noted, a study has been made of American men of science, selected by the order of merit method. The sciences were divided into twelve groups and the number in each was taken approximately proportional to the total number of scientific workers, ranging from 175 chemists to 20 anthropologists. In each science the men were arranged in the order of the value of their work by ten leaders. The average positions and probable errors were then calculated, giving the order in each science. These were interpolated to give a list of about 2000 names, but in the main only the first thousand have been considered. The list was obtained in 1903 and again in 1910. In 1920 it was compiled for the third time, but by a different method, used partly for its scientific interest, partly in order to avoid too great demands on the time of a few leading scientific men and to prevent any inbreeding from a limited number of judges.

The names and addresses of the scientific men included in each science in the two previous selections were sent to those on the list and they were asked to increase it by about 20 per cent. All those who received more than one vote were then asked to make nominations, and those who received the most votes were added to the list up to a number of names twice as large as was to be selected. The names were then sent in alphabetical order to each of those included, and he was asked to check about half the names to indicate those whose work he regarded as of most merit, with a double check for about one in twenty whose work he considered the most important. Some 2000 scientific men were asked to take part in the selection, and about 1000 complied. The probable error of the position of the individuals was nearly the same as before. The measurement of the validity of a vote has application from the decision of a committee to a national election.

The scientific men are thus arranged in the order of the value of their work with a probable error which shows the correctness of the position assigned to each and also measures the differences between them. It consequently becomes possible to measure the scientific productivity of a region of the country or of an institution and its contemporary strength, with the changes that occur at different periods. The single figure giving the gain or loss in position of a scientific man in the course of ten years condenses a great deal of information and is dramatic in its implications. When we put knowledge concerning men of science on a statistical and quantitative basis, we may hope ultimately to determine the hereditary and environmental conditions favourable to the production and to the productivity of workers in science.

There are large variations in the origin and in the present residence of scientific men throughout the United States. Their birth rate per million of population was 109 in Massachusetts, and decreased from that centre to 47 in New York, 23 in Pennsylvania, 9 in Virginia, less than 2 in the Gulf states. Their present residence tends to correspondence with their place of birth, but some cities and states obtain more scientific men than they produce, and conversely. Scientific activity is moving westward. Of younger men added to the list, the birth rate fell in Massachusetts from 109 to 85, in New York from 47 to 36, whereas it increased in Michigan from 36 to 74, in Minnesota from 23 to 59.

In academic production and possession of scientific men, Harvard leads by a wide margin, though the Johns Hopkins has given nearly twice as many doctorates to those who have attained scientific standing. In 1920 there were at Harvard 73 of our thousand leading scientific men. The numbers in other large institutions were—Columbia, 42; Chicago, 39; Yale, 35; Johns Hopkins, 35; Cornell, 33; California, 31. From 1905 to 1920 the net gain was at Yale, 9; at Harvard, 7; at the Johns Hopkins, 5; at California, 4. Chicago and Cornell were stationary; the net loss at Columbia was 18. The men can be weighted, in which case the relative strength of Harvard becomes greater. The ten strongest departments in each of the twelve sciences have been determined, Harvard among universities standing first in mathematics, physics, chemistry, botany, zoology, pathology, and anthropology; second in geology and physiology. The Johns Hopkins had one of our leading thousand scientific men for 37 students. At Harvard the ratio was 1 : 75, at Yale, 1 : 105; at Columbia, 1 : 202. In the fifteen-year period the Department of Agriculture had a net loss of 9, the Geological Survey of 6, the Smithsonian Institution of 5; the Bureau of Standards a gain, of 11. The Carnegie Institution and the Rockefeller Institute had large gains, as had also the industrial laboratories. The movement of scientific men to the research foundations and laboratories is one of the notable changes of the past twenty-five years.

The list of a thousand scientific men permits not only the measurement of scientific merit and a study of the origin and distribution of scientific workers, but also offers opportunity for obtaining vital and other statistics. Thus, to take an example, the average size of the completed family of the scientific men is 2·2. Voluntary control increased from 48 per cent. of marriages prior to 1880 to 70 per cent. of those contracted in the 'nineties. Childlessness was involuntary in two-thirds of the cases; the standardised two-child family was desired in six cases out of seven. Or again, the brother of a scientific man is two hundred times as likely as another to be himself a scientific man.

We need scientific knowledge concerning scientific men and the conditions favourable to scientific work and to the scientific career. In the course of the week during which these remarks are being written, Secretary Hoover in an address to the Society of Mechanical Engineers has stated that the United States is behind most European nations in scientific research, and President Butler in his annual report has stated that Columbia University cannot replace " older scholars of distinction and large achievements," because " a choice must be made from a larger or smaller group of mediocrities." It may be that we are inferior to other nations and that we now produce fewer scientific men of distinction than formerly, but both statements are open to question. The circumstance that they are made by men of wide information and can be neither proved nor disproved shows the urgent need of correct information.

It is the business of psychology to secure such knowledge, to determine how those fit for scientific research can be selected, what training should be given to them, what positions, opportunities, and rewards are most effective. Scientific men should apply scientific methods to their own work and to securing the widest co-operation. Books and journals, including technical publications for scientific men, others that will interest the "average man" in science and in the wider application of the scientific method, are leading agencies. Science Service, for which the American Association shares the responsibility, should be made a large factor in the dissemination of science. But of all agencies for the promotion and diffusion of science, scientific societies are the most important—the national societies in each science, the state and local academies, most of all the association in which these are united and which at its annual meetings and at all times advances the interests of science and of scientific men and impresses on the widest public the weight and magnitude of modern science.

In spite of the limited value for science of direct introspection, our mental life is part of the real world, and is that part which is of the greatest concern to each of us. It may be, as has been suggested, that psychology lost its soul long ago and is now losing its mind; but it cannot lose consciousness. Our perceptions, thoughts, intentions, and feelings are not only elements in sensori-motor arcs; for us they are also the end to which the whole creation moves. So far as production goes, consciousness may be only a spectator; but it is the ultimate consumer. We shall have in due time a scientific psychology of human welfare, of the things that are beautiful, good, and true. But it will not come until we get these things instead of talking about them; for science has meaning and value only in its usefulness. Psychology may supply economic values equal to those of the physical and biological sciences, human values of even greater significance.

Scientific research and the applications of science in the course of 150 years have increased fourfold the productivity of labour; they have doubled the length of life. Science has made it possible for each to work at routine tasks half as long as formerly and at the same time to consume twice as much wealth as formerly. Fourteen hours of labour, shared by women and children, once provided hovels, lice, and black bread for most people, luxury for a few. Seven hours of labour will now supply comfortable homes, warm clothes, and healthful food for all. If the resources provided by science were properly distributed—as they will be when we have an applied science of psychology—there is now sufficient wealth to enable all to share in the desirable luxuries that science has created, and to enjoy in full measure the most nearly ultimate goods of life—home, friends, things to do, freedom, self-respect.

The better lives secured through the increased wealth provided by science, together with the applications of science to hygiene, medicine, and surgery, have doubled the length of life. In the nations of the west, pestilence and famine have lost most of their terrors; of the three evil fates, only war survives from a pre-scientific and barbarous past. Much is crude and ugly in the modern world; atrophied instincts and aborted impulses must be replaced by the products of a science of psychology before living can become free and fine. But those who call our industrial civilisation materialistic and ignoble have narrow thoughts and scant idealism. They fail to imagine what it means in terms of love and suffering that of ten infants born, formerly only two or three survived childhood, while now eight or nine may live to have children of their own.

The applications of science have abolished slavery and serfdom, the need of child labour, the subjection of woman; they have made possible universal education, democracy, and equality of opportunity, and have given us so much of these as we have. Science has not only created our civilisation; it has given to it the finest art and the truest faith. The advancement of science should be the chief concern of a nation that would conserve and increase the welfare of its people.

The Progress of Directional Wireless Communication.

By Dr. R. L. SMITH-ROSE.

FROM the earliest days of practical wireless communication, it was realised that one of the most important services which this art would render to humanity was its contribution towards the safety of life at sea. The possibility of a ship being able to keep in communication with the remainder of the world during the longest voyages, and, in time of distress, to broadcast an appeal for assistance, has removed much of the terror of shipwreck and fire at sea. A later development, which bids fair to rank second in importance to the above, is the direct application of wireless to aerial and marine navigation. There are, broadly, two methods by which a wireless signal may be used to determine the direction of any given fixed point. In the first, the direction of arrival of the signals from any transmitting station is determined by means of a direction-finder. The second method involves the transmission of a rotating beam of large or small angle and its reception on any suitable receiver.

The wireless direction-finder makes use of the fact that in electromagnetic waves travelling over the earth's surface, the magnetic force of the waves is horizontal and perpendicular to the direction of transmission. If a closed loop or coil of one or more turns with its plane vertical is used to receive such waves, the strength of the signal E.M.F. induced in the loop will be proportional to the cosine of the angle between the plane of the loop and the direction of arrival of the waves. Hence, if the loop is rotated about a vertical axis, the strength of the signals received will pass through successive maximum and zero values at intervals of 90°. A consideration of the case shows that the rate of change of the resulting signal strength is greatest when passing through the zero position, which is therefore the most sensitive condition for the determination of the direction of arrival of the waves. In this zero position the plane of the loop is perpendicular to the direction of the incoming waves and thus of the transmitting station.

There are three practical forms of wireless direction-finder in use to-day operating on this fundamental principle of the simple rotating loop: and it can be shown, both theoretically and experimentally, that the accuracy is of the same order for all the systems, each of which has its own field of application. The limiting accuracy to which the modern direction-finder has been developed is about 1°, which, it may be remarked, is ample for the present-day needs of navigation.

Apart from any defects of instrument design and construction, the direction-finder is subject to errors which are conveniently divided into three classes. In the first class are those due to local conditions surrounding the instrument, such as metal-work, overhead wires, and trees. The currents set up in such objects create a secondary field in the neighbourhood which is superimposed on the primary field of the waves, producing a resultant field the direction of which may deviate seriously from that of the original field. It is usual in selecting a site for a wireless direction-finder on land to attempt to avoid such sources of error, but it is seldom that an ideal site can be found. The small residual errors which are experienced are taken into account by calibrating the station on various fixed transmitting stations. Instances in which an error due to the site of the installation is unavoidable are those of ships and aircraft. In these cases the error in apparent direction varies in an approximately sine-wave form with the direction of the incoming waves relative to the fore-and-aft line of the ship. In such installations, either a correction curve is prepared from observations taken while the ship is swung on a fixed transmitting station, or the error is approximately compensated for by a suitable circuit arrangement.

The second class of error is in the nature of a surface refraction effect and is encountered when the path of the waves lies approximately parallel to the boundary between land and sea. If observations are made on wireless waves crossing a coast-line, the direction-finding instrument indicates that the waves in crossing from sea to land experience a deviation in a direction towards the normal to the coast-line at the point of transit. No satisfactory theoretical explanation of this phenomenon has yet been given, but as the error is frequently of the order of 5°, it is customary to avoid, wherever possible, the taking of bearings on waves travelling in a direction approaching that of a coast-line.

The type of error in the third class presents more difficulty in accurate work, on account of its very erratic and variable behaviour. Fortunately this class of variable error is encountered only when the range of transmission exceeds certain minimum values, beyond which the apparent direction of arrival of the waves is subject to somewhat erratic variations, the frequency and magnitude of which are dependent to a limited extent upon the wave-length employed, the distance of transmission, and also upon the season and time of the day at which the observations are made. During the hours of full sunlight in summer, these variable errors have a maximum value of about 4°. As sunset is approached they increase in frequency and magnitude, and from about one hour before sunset until about one hour after sunrise the apparent direction of arrival of the waves varies rapidly on either side of the true direction over an arc which is often 10° or 20° and may occasionally exceed 90°.

The theory which has been developed to explain these errors rests on the same basis as the theory of the fading of wireless signals and of the mode of propagation of wireless waves around the earth's surface. This theory assumes that the upper ionised regions of the atmosphere are operative in deflecting wireless waves arriving from a transmitting station in such a manner that they are eventually returned to the earth's surface. A direction-finding station will thus receive waves from the transmitter not only horizontally along the earth, but also from a downward direction. If, as is possible from several causes, the plane of polarisation of the downcoming waves differs from that normally encountered in transmission along the earth's surface, the direction of the horizontal component of the resultant magnetic field due to the two arriving waves will in general not be at right angles to the direction of transmission. Thus, although there has been no departure of the line of travel of the waves from the vertical plane connecting transmitter and direction-finder, the latter will indicate an error in the apparent direction of arrival. This theory is being supported by the accumulation of a large and varied amount of experimental evidence, and the investigations concerned provide an excellent means of studying the physics of the upper atmosphere.

DIRECTION-FINDERS IN NAVIGATION.

The discovery of the existence of these errors in the course of the development of direction-finding during the War inspired a lack of confidence in this art among those responsible for marine navigation. Systematic research carried out during the last few years has, however, brought to light a state of affairs which has resulted in the reinstatement of the wireless direction-finder as a direct aid to seamen. While the instrument may be used at ranges of several hundred miles to give a general idea of a ship's position, it is in the making of a landfall after an open-sea voyage, or in the navigation of harbour entrances during bad or foggy weather, that the wireless direction-finder is in demand. The ranges at which it is required to operate with accuracy are seldom greater than 50 miles, and never greater than 100 miles. Now the variable errors described above are only experienced when the range of transmission exceeds 30 miles overland, or 80 to 100 miles oversea. Hence, by a suitable choice of shore transmitting stations, the ship's direction-finder can be used to operate on waves travelling entirely over sea, with the result that, within its required range, about 95 per cent. of the observed bearings fall within a 2° limit of error, which is found to be adequate for most navigational purposes.

During several years' observations, no effect of fog or other surface weather conditions has ever been noticed in wireless direction-finding, which is again fortunate for its use in navigation during times when visual observations are impracticable.

In the application of the direction-finder to aircraft, similar remarks apply as to its accuracy, with one important addition. When the direction-finder is operated on the ground on the transmissions from a machine in the air, the observed bearings are liable to error when the angle of elevation of the machine at the ground station exceeds a small value. This error is caused by the operation of downcoming waves on the direction-finder, but is evidently only appreciable for very short range transmission. The limited amount of experience with direction-finders used in the aircraft itself appears to show that these are destined to be of great service in the future of aerial navigation.

Turning now to other means by which directional wireless may be used in connexion with navigation, we have first the scheme which is practically an inversion of the above systems; that is, a rotating loop or its equivalent is used at the transmitting end and the reception of the signals is carried out on an ordinary aerial. When a closed loop or frame coil with its plane vertical is used for transmission purposes, the variation along the earth's surface is a maximum along a line through the plane of the coil and decreases according to a cosine law to a zero value along the axis of the coil. If, therefore, the coil is rotated about a vertical axis, the strength of signals received at a distance on an ordinary aerial will vary from a maximum when the coil is pointing towards the receiver to a minimum or zero value when it is at right angles thereto. In the practical operation of the device the coil transmitter is rotated at some convenient uniform rate, and arrangements are made for characteristic signals to be transmitted as the coil passes through two positions such as the north-south and east-west lines. By the use of a stop watch at the receiver, the times of rotation of the coil from one of these positions to the minimum signal position can be determined, together with the time of complete rotation. A simple calculation then serves to obtain the direction of the transmitting beacon from the receiver.

The great advantage of this system is that any ship or aircraft which is provided with a wireless receiver can obtain directional observations on these transmitters, and if a suitable distribution of the latter could be arranged, the method would be very useful for navigational purposes. Although it was developed in Germany before the War and an organisation of rotating beacon transmitters was set up, the system has of recent years only been used for experimental purposes, and its commercial application has still to be realised. It may be mentioned here that both this type of directional transmitter and the directional receiver referred to previously can be provided with a simple circuit modification which results in only one signal minimum being produced in a rotation of the coil through 360°. This "sense-finding" attachment results in the removal of the 180° ambiguity which is otherwise inherent in these methods.

The development and use of the above directional systems has been carried out on the wave-lengths chiefly used for communication purposes in aerial and marine wireless, *i.e.* approximately from 300 to 3000 metres. As a result of the development of the thermionic valve to a high degree for both transmission and reception purposes, it has become possible to extend the practice of wireless communication to very much shorter wave-lengths. Among the numerous vistas of development thereby opened up, not the least important is the practicability of resorting to the use of reflectors for concentrating the radiated energy in the required direction of transmission. By the use of suitable reflectors at both the transmitting and receiving end of a point-to-point communication link, the resulting concentration of wireless wave energy can be made equivalent to a magnification of several thousand times as compared with the ordinary transmitter which radiates its energy equally in all directions. This advantage, combined with the inherent properties which waves lying within certain bands of wave-lengths between 15 and 100 metres appear to possess for travelling through the upper atmosphere to great distances with very small attenuation, has already caused a revolution in ideas as to long-distance wireless communication. The resulting opening-up of a large number of fresh communication channels has come as a great boon to wireless engineers struggling with an already congested ether.

THE WIRELESS BEACON.

By the use of waves of length still shorter than those mentioned, it becomes possible to utilise another principle in applying directional wireless to navigation purposes. This consists in combining the aerial system of a wireless transmitter with a suitable reflector so that a fairly concentrated beam of wireless waves is sent out in one direction, which is varied by the regular rotation of the whole arrangement. We have here literally a wireless lighthouse, since it is exactly analogous to the rotating beam of light emitted by certain lighthouses around our coasts. Now it is a well-known optical law that for a reflector to be effective its dimensions must be at least comparable with the wave-length. Hence it is evident that for the rotation of the reflector to be at all practicable, the wave-length employed must be quite small.

In the two revolving beam transmitters which have been set up in the last year or two, the wave-length employed is about 6 metres. In the first station erected at Inchkeith, Firth of Forth, the aerial is a straight vertical wire erected in the focal line of a cylindrical parabolic reflector system of vertical wires. In the more recent station erected at the South Foreland, the aerial system comprises a number of energised aerials arranged in a plane, and in front of a similar parallel system of reflecting wires. The result in each case is the transmission of a beam of limited angle which is rotated uniformly at a rate of about one revolution per minute. Any ship fitted with a suitable receiver for the wave-length employed will then only receive signals as the beam flashes past its aerial. From the code signals heard the direction of the beam at that moment may be read from a simple chart. The range of the station is necessarily somewhat limited, owing to the great absorption of energy of such short waves by the earth. In experiments carried out a short time ago, it was claimed that a maximum range of 100 miles oversea could be obtained.

A great advantage possessed by this system over those previously mentioned is that it should be free from any errors due to its waves being deflected from the upper atmosphere. This fact may prove to be very important in securing a practical working range well in excess of that given by the waves travelling along the earth's surface. An advantage of the use of the short wave-length is the comparative freedom from interference which is experienced at the receiver. On the other hand, the use of such short waves may result in serious errors due to the coastal refraction effect previously mentioned, and to deviation of the waves by such obstacles as cliffs and buildings acting as reflectors.

Helium in Canada.

By Prof. J. C. McLennan, F.R.S., University of Toronto.

IN 1916, at the request of the Admiralty, and in collaboration with my colleagues, Profs. Satterly, Burton, and Dawes, I investigated the natural gases of Canada with the view of ascertaining the amount of their helium content. The gases with the highest helium content were found at that time to be in Ontario and in Alberta. In neither Province was any considerable supply of gas located that contained more than 0·36 per cent. of helium. During the years 1917–1920, with the assistance of Mr. John Patterson, of the Meteorological Office, Toronto, I designed and successfully constructed and operated a semi-commercial plant for extracting helium from natural gas. The gas we worked upon was obtained from an extensive field situated near Calgary, Alberta. During the operation of this plant we extracted in all from 15,000 to 20,000 cubic feet of helium having a purity of 90 per cent. When the Cryogenic Laboratory was instituted in the University of Toronto in 1922, the helium extracted at Calgary became available, and we succeeded in liquefying helium early in January 1923.

Since 1916 many new gas fields have been opened up in Canada, and about two years ago the Dominion Mines Branch decided to make a re-examination of the Canadian natural gases for helium. Mr. R. T. Elworthy was invited to undertake this task, and has carried it through most thoroughly and expeditiously. He found that in Alberta, while some of the natural gases contained less than 0·1 per cent. of helium, a number of them contained so much as 0·25 per cent. In some cases in this Province the helium content ran so high as 0·34 per cent. In New Brunswick none of the natural gases investigated was found to contain more than 0·064 per cent. In Ontario the natural gases varied considerably in their helium content. The gases of Lambton, Kent, and Essex Counties were found to contain not more than 0·15 per cent., while those in the counties of Brant, Haldiman, Lincoln, and Welland were found to have a helium content of from 0·25 per cent. to 0·35 per cent. In the County of Norfolk considerable supplies of gas were produced which ran from 0·4 per cent. to 0·5 per cent. in helium. The gas richest of all in helium was found in Peel County, the content being slightly more than 0·8 per cent. In this field three wells have already been sunk, and the gas is drawn from a horizon approximately 600 feet deep. The wells are consequently shallow, and though the gas supply is only moderate in amount, it has been estimated that the three wells will provide at least 100,000 cubic feet of helium per year.

With the view of rendering the supply of helium permanently available for research work in the University of Toronto, the Hon. the Premier of Ontario recently announced that, under an Order-in-Council, the Government of Ontario had secured, for the Crown, the products of the three wells mentioned, and the natural gas rights as well over a large block of land in the immediate neighbourhood of the wells.

The National Research Council of Canada has endorsed the policy adopted by the Government of Ontario, and is co-operating with the University of Toronto and other organisations in a scheme to establish a helium extraction station in the Peel County gas field, with the object of providing helium for research workers requiring the gas in Canada and probably in other parts of the British Empire as well.

It is fortunate that a supply of helium has been found in such a convenient locality—only some thirty-five miles from Toronto—for although the Government of the United States has extracted enormous amounts of helium from the natural gases of the Western States, its export from the United States is prohibited by law.

If we succeed in making the financial arrangements we have in mind, we hope to be in a position to provide, in the near future, ample supplies of helium for scientific investigations within the Empire.

Obituary.

Prof. J. G. M‘Kendrick, F.R.S.

EMERITUS-PROFESSOR JOHN GRAY M‘KENDRICK, who died in Glasgow on January 2, was born in Aberdeen in August 1841. By the death of his parents he was at a very early age thrown upon his own resources. When he was but thirteen years of age he was sent to spend a summer with his grandfather at Braco in Perthshire, where, herding sheep daily from 5 A.M. to 8 P.M., he learned to know and love the plants and the animals and Nature in all her moods. Zoology became M‘Kendrick's first scientific study; and the youth of seventeen actually demonstrated his little marine aquarium at a conversazione of the British Association which met in Aberdeen in 1859. Here he saw for the first time Faraday, Owen, Murchison and Huxley; science had begun to call him to herself.

Some one suggested that M‘Kendrick should qualify for the medical profession, and so, while still apprenticed to a lawyer in Aberdeen, he would rise at five and study until ten, when the duties of the desk claimed him for the day. After passing the "Medical Prelim." at Aberdeen, he went to Edinburgh in 1861 to enter upon the serious study of medicine. Here he heard Goodsir lecture; saw Turner and Joseph Bell ("Sherlock Holmes") demonstrate; listened to Simpson with his European reputation, to Laycock who was a psycho-analyst sixty years ago, and to Christison who was making toxicology a science. M‘Kendrick took Goodsir's medal in 1863, and was a prizeman in medicine, obstetrics and surgery. In 1864 he graduated M.D. with distinction at the University of Aberdeen. Years afterwards he summarised his medical course:—"no laboratories, no apparatus, no histology, no bacteriology, and *seven* different theories of inflammation."

After a few months at the Chester General Infirmary, M‘Kendrick obtained the position of surgeon to the

Eastern Dispensary in Whitechapel; and as he passed through London to take up his duties he saw the crowd witnessing the execution of Müller for the murder of Mr. Briggs in 1864. For the pain, squalor and vice of Whitechapel, M‘Kendrick exchanged the purity and serenity of Glen Nevis, for he became surgeon to the Belford Cottage Hospital at Fort William in 1865. It was in Lochaber that he met Hughes Bennett accidentally, and soon became his assistant. From 1870 until 1873, when Bennett's ill-health compelled him to winter abroad, M‘Kendrick had sole charge of the university classes at Edinburgh, which he conducted with marked success. Bennett resigned in 1873, and Rutherford was recalled from King's College, London, to fill the vacant chair, so that M‘Kendrick applied for and obtained the lectureship in physiology at Surgeons' Hall, and that at the Dick Veterinary College, Edinburgh. Here it was that he met James Dewar, with whom was begun that joint research which resulted in the discovery of the electric current produced in the retina and optic nerve when a beam of light was allowed to enter the eye.

For the first time in the history of physiology a current of action had been demonstrated in a sensory nerve by the normal stimulation of its end-organ. That Holmgren in Upsala made the same discovery about the same time was, of course, unknown to the Scottish workers. Dewar and M‘Kendrick also investigated the physiological action of chinoline and the pyridenes, becoming once more pioneers, this time in researches into the correlation between chemical structure and physiological effect. In 1872 M‘Kendrick visited Germany, and met Schultze, Pflüger, Du Bois-Raymond, Ludwig and Helmholtz. His "Life of Helmholtz" is perhaps his best piece of writing; it is an admirable account of a life with little incident in it apart from the scientific discoveries.

In 1876 M‘Kendrick was appointed to the chair of the Institutes of Medicine at the University of Glasgow; and here a Department of Physiology was created out of a lecture-room, a sphygmograph, a few microscopes and some diagrams.

M‘Kendrick was one of the most agreeable scientific lecturers Scotland has produced: his discourse had all the charm of a tale pleasantly told. In 1871 he had been elected a fellow of the Royal College of Physicians of Edinburgh. In 1881 he was appointed Fullerian professor of physiology at the Royal Institution, in which capacity he delivered many Friday evening discourses, as well as Christmas lectures to the children, and a valuable series on the history of physiology. In 1882 he received the degree of LL.D. from his Alma Mater; and two years later was elected into the Royal Society on the Council of which he afterwards served. He had been president of the Royal Society of Edinburgh, of the Section of Physiology of the British Association, of the Glasgow Philosophical Society; and he acted as examiner in a large number of universities. He delivered two courses of Thomson lectures at the Free Church College at Aberdeen.

M‘Kendrick wrote with ease; he was the author of the articles on ear, eye, senses, stereoscope, longevity and nervous system in the "Encyclopædia Britannica," as well as of "The Outlines of Physiology" published in 1878, and ten years later of a "Text-book" in two volumes splendidly illustrated. In conjunction with his assistant, Dr. Snodgrass, he wrote an interesting volume on "The Physiology of the Senses."

From 1892 onwards M‘Kendrick, who had always been interested in physiological acoustics, investigated the tracing on the surface of the wax cylinder of the phonograph by a photographic method. Later he devised an apparatus to eliminate the hissing sounds which mar the music reproduced by that instrument. M‘Kendrick was very fond of music, of poetry and of animals. He published a volume of devotional verse. His disposition was that of a deeply religious and reverent man who, though enjoying fun, disliked frivolity. His sympathies were wide, his friendships many, his capacity for bringing the best out of every one conspicuous. He urged moderation in the use of strong drink; some of his best addresses are those dealing with this subject.

M‘Kendrick married in 1867 a daughter of W. Souttar of Aberdeen, who died in 1898. He is survived by two sons—Dr. J. S. M‘Kendrick of Glasgow, and Colonel Anderson M‘Kendrick, I.M.S. (retired), director of the Laboratory of the Royal Colleges at Edinburgh—and by one daughter.

D. Fraser Harris.

We regret to announce the following deaths:

Prof. E. G. Browne, Sir Thomas Adams professor of Arabic in the University of Cambridge and fellow and president of Pembroke College, known for his work on Persian literature and on the history and literature of oriental religions, on January 5, aged sixty-three years.

Dr. R. Caton, C.B.E., pro-chancellor and emeritus professor of physiology in the University of Liverpool, and vice-chairman of the Liverpool School of Tropical Medicine, on January 2.

Rev. George Henslow, lately professor of botany to the Royal Horticultural Society, and from 1882 until 1904 president of the Ealing Natural History Society, on December 30, aged ninety years.

Prof. Martin Kirchner, who was prominently associated with the anti-tuberculosis campaign and with the framing of the German laws relating to infectious diseases, on November 11, aged seventy-one years.

Mr. Frank Morey, honorary curator of the Prince Henry of Battenburg Memorial Museum at Carisbrooke Castle, Isle of Wight, and editor and joint author of "The Guide to the Natural History of the Isle of Wight," on December 29, aged sixty-seven years.

Dr. James Murie, formerly assistant-secretary and librarian of the Linnean Society, and naturalist to Consul Petherick's expedition of 1861 to Gondokoro, on December 21, aged ninety-five years.

Erratum.—Mr. Edgar R. Waite, the Director of the South Australian Museum, Adelaide, informs us that the details given in the obituary announcement referring to Mr. A. R. McCulloch, which appeared in Nature of October 24, 1925, p. 620, are incorrect. Mr. McCulloch was zoologist at the Australian Museum, Sydney, where he devoted himself to research on fishes and crustaceans, and his death occurred on August 31, at the age of about thirty-eight years.

News and Views.

PROF. W. GARSTANG, whose address on "Wordsworth's Interpretation of Nature" is published as a Supplement to this week's issue of NATURE, is both a naturalist and a poet, and is therefore appropriately equipped as an exponent of one who made Nature and man his chief poetic theme. Wordsworth felt himself to be a great high priest of Nature, and his spiritual insight was deep and penetrating. In the application of scientific truth to poetic purpose, he was as accurate and trustworthy as Tennyson, but not so rich or minute in his allusions to scientific knowledge. We do not for a moment suggest that the worth of poetry can be measured by the use made of such knowledge, but new natural phenomena and conceptions can extend the range of poetic thought and inspire that emotion which expresses itself in enduring verse. "Poetry," said Wordsworth, "is emotion recollected in tranquility," and it differs from science in being the expression of individual feeling as an end in itself and not as a means of securing general assent to particular conceptions or interpretations of the theme. There is plenty of imagination in science, but it is disciplined and unemotional, and is put to the test of observation with the view of arriving at natural truths, whereas in poetry its object is the communication of pleasure by beautiful phrase or creative fancy. In ornithology there is but one description of the skylark, but in poetry there are scores, and each has a note of its own. That is why we find such poets as Keats, Shelley and Wordsworth interpreting the aspects and operations of Nature in ways that are differently beautiful. Keats by sympathetic human imagery, Shelley by changefulness and its symbolism, and Wordsworth by richness of allusions to everyday aspects of natural objects and events. We are sure that Prof. Garstang's illustrations of Wordsworth's style and genius will be read with pleasure by lovers of literature as well as of science.

THE searchlight of public opinion begins to shine upon the mathematical tripos. A few days ago Prof. G. H. Hardy, in his presidential address to the Mathematical Association, gave it as his considered opinion that the tripos should be abolished. It is not because mathematics are in a better state at Oxford than at Cambridge that he directs his fire against his old university and not his new one, it is because the Cambridge examination is the more important one. Prof. Hardy considers that the nature of the mathematical tripos examination prevents any serious study of mathematics and causes candidates to spend their time learning tripos tricks instead. So bad is the effect of this that among mathematicians of world fame, we produce only about a twentieth of the number that our record in more wholesome times would entitle us to expect. To determine whether a candidate is worthy of a degree, Prof. Hardy would require him to send in a dissertation and judge him upon that. He would in fact adopt the usual continental method. This method of a degree by thesis is also not unknown in Great Britain. Most of our universities allow it as a method for higher degrees. Most of them it is true require the first degree to be by examination, and only in the London B.Sc. do we find an instance of a first degree that can be obtained by thesis.

PROF. HARDY'S cure is a more drastic one than that proposed in our leading article of May 10, 1924, p. 665, entitled "Mathematical Physics in University and School." In that article we proposed to broaden the mathematician's studies by including physics, and to make this possible in the three years at the disposal of the student by the severest pruning of both mathematics and physics. Now pruning is always a delicate and difficult operation, and we are inclined to believe that Prof. Hardy's cure is a better one. It has, moreover, the advantage of mending ills that we had not considered. Our complaint was only against the narrowness of the range of the mathematician's studies, his is against the method of treatment of the whole subject. A system in which a candidate, after taking the first part of the mathematical tripos, would be allowed to show up a dissertation instead of taking the second part, is no great departure from the traditions of British universities, since they do already in certain cases allow degrees by thesis. To aim at such a system would seem an appropriate first objective; and when such a system had been adopted and had had some years trial, it would be time enough to consider whether it was right or wise to go further and allow an alternative also to the first part of the examination.

FOR the meeting of the British Association in Oxford, August 4-11, under the presidency of the Prince of Wales, the Council has appointed the following sectional presidents: Section A (Mathematics and Physics), Prof. A. Fowler, professor of astrophysics in the Imperial College of Science and Technology; Section B (Chemistry), Dr. J. F. Thorpe, Yarrow research professor of the Royal Society and professor of organic chemistry in the Imperial College of Science and Technology; Section C (Geology), Dr. S. H. Reynolds, professor of geology in the University of Bristol; Section D (Zoology), Prof. J. Graham Kerr, regius professor of zoology in the University of Glasgow; Section E (Geography), the Hon. W. Ormsby-Gore, M.P., Colonial Office; Section F (Economics), Sir Josiah Stamp; Section H (Anthropology), Dr. J. H. Fleure, professor of geography and anthropology in University College, Aberystwyth; Section I (Physiology), Prof. J. B. Leathes, professor of physiology in the University of Sheffield; Section J (Psychology), Dr. J. Drever, reader in psychology in the University of Edinburgh; Section K (Botany), Dr. W. Bateson, director of the John Innes Horticultural Institution; Section L (Education), Sir Thomas Holland, rector of the Imperial College of Science and Technology; Section M (Agriculture), Sir Daniel Hall, chief scientific adviser to the Ministry of Agriculture. The name of the president of Section G (Engineering) will be announced later.

THE extent to which the technical intelligence service attached to the manufacturing community of Great Britain has been augmented since the War by the new industrial research associations is well illustrated in a paper read before the Institution of the Rubber Industry on December 7 by Dr. S. S. Pickles, the Chairman of the Library Committee of the Research Association of British Rubber and Tyre Manufacturers. The paper dealt with the importance of such a service to the rubber industry, and described some of the work that the Rubber Research Association is doing in this respect. In the short period of its existence the Association has built up a Library which not only possesses a representative reference collection of books, pamphlets, and periodicals (claimed by Dr. Pickles to be without an equal in Great Britain), but also acts as a very complete information bureau on all matters relating to the rubber industry and trade. The Library is provided with a comprehensive classified card index to the contents, which enables it at short notice to supply references to all published information on any branch of the subject, and in addition issues monthly to all its members a *Summary of Current Information* in which are given more or less lengthy abstracts of articles appearing in the scientific and technical press, and of English and foreign patents, notices of new publications and of book reviews, and lists of English patent applications and acceptances. The size of this publication, which will comprise well over 400 pages for the current year, shows how increasingly serious a problem it is for the specialist to keep in touch with what others are doing in the same field, and emphasises once more the vital necessity for the provision of adequate compilations of this nature in all branches of science and technology. Some of the best work in this direction being done at the present time lies to the credit of the research associations, and though the records are not usually available to the general public, their circulation amongst the majority of those intimately connected with the industries concerned cannot but have far-reaching results.

THE use of hydrogen in large-scale chemical manufacture is a comparatively recent development, of which the importance is growing rapidly. Production of synthetic ammonia entails the greatest consumption, but large quantities are also used for hydrogenating liquid oils to convert them into solid, edible fats. The manufacture of hydrogen for the latter purpose was discussed at a meeting of the Chemical Engineering Group of the Society of Chemical Industry on January 8, when Mr. A. E. Knowles read a paper on the electrolytic method of production. The Lane process of making hydrogen, by passing steam over heated iron or a carbonaceous iron-ore and then reducing the iron oxide with water-gas, has fallen out of use for economic reasons, and the Haber-Bosch process of passing water-gas and superheated steam under pressure over a catalyst, though cheaper than any other, is unsuited for producing hydrogen to be used for hydrogenation, because it is always contaminated by much nitrogen. In Mr. Knowles's opinion, the electrolysis of distilled water is alone suitable, and in his paper he described in detail the electrolytic plants in use at Port Bromboro', in Cheshire, and at Bussi, in Italy. The outstanding merits of this process are great purity of the hydrogen, economy in labour and wear and tear of plant, no leakages of electricity or gases, and very cheap production, if cheap electricity is available, and if there is a ready market for the by-product oxygen. Dr. A. C Thaysen's paper on the production of hydrogen by micro-organisms summarised the history of this method, and gave data concerning the process used in the Royal Naval Cordite Factory at Holton Heath during the War for making acetone by fermenting maize-starch and other amylaceous material. This process yields, in addition to acetone, *n*-butyl alcohol, organic acids, and carbon dioxide, 1·60 per cent. of hydrogen, or 5·5 cubic feet per lb. of grain fermented. A comparatively small plant consuming 20 tons of grain per day produced about 250,000 cub. ft. of this gas at an estimated cost of about 2*s*. per 1000 cub. ft. for collection and purification. Both the electrolytic and the fermentation processes are of especial interest, because they do not involve the use of any fuel.

CAPTAIN P. P. ECKERSLEY, the engineer to the British Broadcasting Company, gave an interesting lecture on January 7 to the Institution of Electrical Engineers on "Past, Present, and Future Development in Wireless Telephony." As a means of communication between individuals, Capt. Eckersley does not anticipate any rapid development in radio telephony, the future of the art will lie mainly in its applications to broadcasting. If in Great Britain at the present time, we connect a microphone with the net-work of wires each of which terminates at a transmitting station, then one voice can be heard simultaneously by ten million people. In Capt. Eckersley's opinion, a final scheme for Great Britain would rely on line relay stations at Glasgow, Leeds, London, and possibly Bristol or Gloucester. The other stations would be connected with these by suitable land wires. The system would be completed by interconnecting Glasgow with Leeds, Leeds with London, and London with Bristol by trunk lines. Future development seems to be leading in the direction of a few stations having large power outputs. Owing to the fact that only about 100 wave-lengths are available for broadcasting, the allocation of them internationally is still a vexed question. He had recently suggested that 82 of them should be allocated to the most important stations, and that sixteen wave-lengths should be reserved for group working. By suitably distributing these sixteen wave-lengths amongst stations of moderate power, there would be little serious interference. If stations could work on exactly the same wave-length, no heterodyne note would be audible. The difficulties in the way are great, but Capt. Eckersley has hopes that they will be overcome. In choosing a site for substations in Great Britain, the criterion must be the crystal set. If the listener can receive broadcasting on a crystal set from a given station, there will be little risk of him suffering appreciably from interference.

THE present exhibit in the house devoted to objects of special interest at the Royal Botanic Gardens, Kew, illustrates living plants of economic value. It includes plants which produce rubber, balata and chicle gum, and a Wardian case packed with young para rubber plants is also exhibited in order to illustrate the manner in which the para rubber and other economic plants have been sent from Kew to all parts of the Empire. Plants of tea, coffee, cacao, and Paraguay tea (the Yerbe de Maté) are examples of the plants yielding beverages. Amongst the fibre-producing plants shown are sisal (Agave), silk grass, China grass or ramie, Manila hemp (*Musa textilis*), Mauritius hemp (Furcræa), and the palm yielding raffia or bass (*Raphia vinifera*). Timbers are represented by young plants of teak, the true mahogany (Swietenia) from Honduras, West African mahogany (Khaya), and West African cedar. Other plants of economic importance exhibited are those yielding cocaine, quinine, ipecacuanha, eucalyptus oil, cloves, cinnamon, camphor, olives and pepper. A plant is also shown of *Tarahtogenos Kurzii*, one of the sources of chaulmoogra oil, which is now being used in the treatment of leprosy. The notices with the plants indicate their countries of origin and also the part which has been played by the Royal Botanic Gardens, Kew, in introducing such plants of economic value to the various parts of the British Empire.

ON December 18 Prof. T. H. Havelock read an interesting paper before the North-East Coast Institution of Engineers and Shipbuilders on "Some Aspects of the Theory of Ship Waves and Wave Resistance" The first two sections of the paper must be of great interest to those who, engrossed in the more immediately practical problems that present themselves, have not the opportunity of studying the mathematical theory for themselves or of keeping abreast of its developments. In the first section, it is shown how calculations with travelling pressure disturbances illustrate such problems as the variation of wave resistance with speed, the interference of bow and stern waves and the effect of shallow water. In the second section, the hull of the ship is regarded as equivalent to a certain distribution of sources and sinks in the fluid and this enables such questions as the effect of the form of the water-line section, the length of the parallel middle body, and the effect of variations in draught to be treated. Some notes on the detailed mathematical calculations as they have appeared in Prof. Havelock's published papers is dealt with in an appendix. It is not claimed that the theory has reached a stage at which any new and important practical results can yet be deduced but rather that the general conformity of the conclusions from a pure hydrodynamical theory with known practice is satisfactory from the point of view of future development.

WE regret to learn from the *Chemiker-Zeitung* that a fatal accident has been caused by the unexpected explosion of a mixture of carbon disulphide and liquid air. Organic liquids of many different types, *e.g.* ether, chloroform, ethyl acetate, petroleum, pyridine, etc., have been employed at various times in conjunction with liquid air for the purpose of preparing freezing mixtures, and, so far, explosions have only resulted when carbon disulphide has been used. When this substance is dropped into liquid air there is formed on the surface a crust which may hinder evaporation and thereby cause an explosion unless the crust be pierced as quickly as it is formed. There appears, however, to be some further cause of instability, which has not yet been explained. Prof. W. Biltz, of the Technische Hochschule in Hannover, states that on November 16 a skilled experimenter, Dr. Asbrand, was preparing the mixture in a Dewar flask and had carefully observed all the usual precautions, when the flask suddenly exploded. He was severely hurt, and he succumbed to his injuries on November 28. Dr. Asbrand, who was only twenty-eight years of age, had studied at the University of Göttingen and later at Rostock under Prof. Walden. He had only commenced work at Hannover at the beginning of the present academic year.

MR. DAVID GREENHILL, the Director and General Manager of the Sun Engraving Company, in a lecture before the Royal Society of Arts (published in the Society's journal, December 25), said that colour printing of to-day is done chiefly by lithography, offset, and the three-colour process, the last almost exclusively by letterpress methods, though the photographic principle of the three-colour process is being increasingly used to develop offset work, and also more recently to develop photogravure in colour. The three-colour process is certainly the greatest advance in colour printing of recent years, and with scientific photography and colour selection, skilful fine etching, and very careful machining or printing, it seems to be capable of reproducing almost anything in the way of pictorial representations in colour. The lecturer claimed for British photo-engravers and printers the first place in quality of three-colour process work, though our position is successfully contested in America, Germany, and France, except perhaps in the fine attention to detail and finish. Photogravure, "the most beautiful method of printing yet evolved," has made more rapid strides abroad than Great Britain. It promises to solve the paper difficulty of the letterpress method, which needs a smooth surface, as it readily gives fine results on almost any uncoated paper, and it overcomes various difficulties connected with the inks used in the letterpress method.

IT was suggested in a paragraph in NATURE of January 2, p. 25, that platinised glass might be used instead of neutral tinted glass for solar telescope work. Messrs. Hawksley and Sons, 83 Wigmore Street, Cavendish Square, London, W.1, write to say that they are in a position to supply platinised glass discs of various densities. The Rheinberg methods are employed.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A professor of political science at the London School of

Economics—The Academic Registrar, University of London, South Kensington, S.W.7 (January 22). A medical superintendent in the Infectious Hospitals Service of the Metropolitan Asylums Board—Clerk to the Metropolitan Asylums Board, Victoria Embankment, E.C.4 (January 26). An electrical engineer and electric inspector for the public works department of the Government of Bihar and Orissa—The Secretary to the High Commissioner for India, 42 Grosvenor Gardens, S.W.1 (January 29). An assistant engineer and a junior assistant engineer at the Fuel Research Station, East Greenwich, for research work in connexion with coal purification and internal combustion engines respectively—The Secretary, Department of Scientific and Industrial Research, 16 Old Queen Street, Westminster, S.W.1 (January 30). A forestry inspector in the Lands and Agriculture Department of the Irish Free State—The Secretary, Civil Service Commission, 33 St. Stephen's Green, Dublin (January 30). Sir Ernest Cassel readerships in economic geography and in foreign trade at the London School of Economics—The Academic Registrar, University of London, South Kensington, S.W.7 (March 9). A director of research in animal diseases under the Animal Diseases Research Association—The Secretary, 83 Buccleuch Street, Glasgow (March 27). A computer for the Cadastral Framework Party, Gold Coast Survey Department—Crown Agents for the Colonies, 4 Millbank, S.W.1 (quoting M/13965). A chief engineer for the Public Works Department of the Government of Nyasaland—Crown Agents for the Colonies, 4 Millbank, S.W.1 (quoting M/14046).

Our Astronomical Column.

The Total Eclipse of the Sun, January 14.—It is hoped that fine weather has favoured the various expeditions sent to stations on the path of totality passing from East Africa across the Indian Ocean to Sumatra and Borneo. One matter of interest is the shape of the corona, which is known to vary in a cyclical manner with the sunspots, flocculi, and prominences. This eclipse, occurring about midway between sunspot minimum and maximum, may be expected to show a type of corona which is intermediate between the characteristic minimum type, with polar "brushes" and extended equatorial streamers, and that of the maximum type in which the distribution of the corona is more concentric with the sun's disc.

The finer details of the inner corona have sometimes been observed to show local structures which were apparently related either to sunspots, flocculi, or prominences near the limb at the time of eclipse. It may be noted that, on January 14, the region of the sun containing the large sunspots which crossed the central meridian on December 25, was within a short distance of the limb at position angle 106° east of the north point of the disc.

The January Meteoric Shower.—Mr. W. F. Denning writes: "The weather proved unfavourable for observation on January 3. There were, however, a few brief intervals of clear sky between successive storms at Bristol. About 20 meteors, including 17 Quadrantids, were observed, and they were mostly brilliant objects with long flights and fairly slow motion. The largest meteors were seen at $6^h\ 16^m$, $6^h\ 21^m$ and $6^h\ 50^m$. At $7^h\ 18^m$ P.M. a fine object with exceedingly slow motion was seen in Gemini and directed from a southern radiant near γ Eridani. Later in the night the sky was more or less clouded, though there were temporary clearances and occasional meteors were observed.

"At $9^h\ 52^m$ P.M. a fireball was viewed from various south-western stations falling in the northern sky. It was directed from a region of the heavens opposite to that in which the radiant of the Quadrantids was situated. Mr. Corder of Bridgwater observed this object and described it as quite equal to Venus; emerald green in colour with a red flash at the end. Several observers saw the meteor from Bristol, and I am collecting details with the view of finding the height, velocity, and radiant point.

"On January 4 unsettled weather continued and the prevalence of clouds frequently interrupted watching. Among the meteors observed were five certain Quadrantids, thus proving the shower's active sustenance. In fact, the evidence obtained this year strongly indicates that this display has lengthened its visible duration in recent times. In 1880, 1886, and some other years, extreme brevity appeared to be a characteristic feature of the shower's richer phase, though occasional shots were directed from the same radiant on later nights of the month, certainly to January 15."

The New Greenwich Sidereal Clock.—The new clock by Short with a free and a slave pendulum, the former in an airtight case, has now been in use for a year, and Mr. W. Bowyer contributed a paper to the Royal Astronomical Society, which was read at the meeting on January 8, in which the performance of the clock is described and analysed.

The rate at the beginning of 1925 was very small, but gradually increased, owing partly to a slight amount of air leakage into the case, which necessitated reduction of the air pressure on one or two occasions.

The clock error could be expressed very exactly by an expression of the form $a + bt + ct^2$. The quantity c remained uniform from January until August, when it underwent a notable reduction, the cause of which is unexplained. It retained the new value until the end of the year.

Dr. Jackson noted that the clock performs so well that it raises the question whether we should not make sidereal time vary uniformly, *i.e.* reckon it from the mean equinox instead of the true, which is affected by nutation. The rate of the former clock was not uniform enough to make the difference an important one.

Star Fission and Cepheid Variability.—Dr. Jeans read a paper at the January 8 meeting of the Royal Astronomical Society, in which he elaborated the suggestion made at the previous meeting that Cepheid variables might be stars in which the process of fission was in progress but uncompleted. He gave an estimate of the duration of this stage as compared with the whole life of the star, and concluded that the result accorded with the observed number of Cepheids. He enumerated several points in which the new theory seemed to fit the facts better than the pulsation theory. The latter seemed to require too large a time-lag for the heat produced by compression in the star's interior to reach the surface. Also he found it difficult to picture the whole star pulsating in a single period. He would rather have expected a complex curve like that arising from the striking of several adjacent notes on the piano.

Prof. Eddington continued to defend the pulsation theory, so the matter is one for further discussion and consideration.

Research Items.

THE MAXIMUM POSSIBLE POPULATION OF THE WORLD.—Sir George H. Knibbs concludes in *Scientia* (Nov. 1925) his examination of the world-problems of population, with special reference to the conditions governing the maximum possible population. He gives various estimates (based upon certain considerations) of the possible population ranging from 2942 millions—if the world's existing population increased in ratio of O. R. Baker's estimate of possible increase in the U.S. agricultural area—to 9792 millions—if all existing arable land in the world could support three persons per acre—and a final maximum of 13,440 millions if an average of a person per 2½ acres applied to the whole land surface of the world. But, as he points out, any one estimate is unsatisfactory, because the possible number must depend upon the world's social and economic organisation, upon ethical considerations governing these, and upon the extension of man's knowledge of Nature, and he briefly examines some of the main issues. Assuming that the present standard of living is retained, together with the present national prejudices and egoisms, Sir George considers it doubtful whether the population will ever reach the 5000 million limit. If man better co-ordinates his efforts so as to involve less expense in non-productive effort, then possibly the advance of science may enable the 7000 million limit to be reached. The friendly study of universal economic conditions and of the adjustment of all territorial and economic relations, together with the advances made through systematised knowledge, would perhaps make possible a population of 9000 millions, though this would leave only a small area available to each individual.

JAVANESE ARCHITECTURE.—In December 1924 at a conference of the Java Institute held at Jogjakarta, one of the questions discussed was the value of the ancient Javanese monuments for the present and future Javanese culture. A report of the discussion appears in a translation by Mary A. Rus in the *Indian Antiquary* for December. Among the speakers, Mr. Maclaine Pont enforced his argument by an analysis of the native and foreign elements in Javanese architecture. The Javanese monuments have many special features which are absent from the Indian buildings, such as the Hala head, the Makara, the spouts. The strong personal element in Indian images gives way in Java to a stereotyped "loveliness." Javanese style is elegant, correct, and accurately balanced, while the Indian is overloaded, overpoweringly vital, more solid, but not pure. The great buildings in Java coincide in date with the struggle for supremacy of the two great dynasties of Palembang and Java, but they represent the spiritual aspirations of a people rather than the feeling of Hindu rulers and upper classes. There must have been an architecture in Java resembling the primitive Jameh style before the Hindu dynasties came. It may be assumed that the Hindu dynasties gained their power in the first instance by missionary propaganda which developed canonical architecture in accordance with Indian proportional outlines. The style of the Javanese school perhaps originated from Central Asia through Indo-China. A close study of the reliefs of the great temple of Borobudur reveals that the sculptors had not the slightest knowledge of Indian structure; that in illustrating Hindu tales, they pictured the persons in complete Javanese surroundings, and this convention was accepted by both priestly and civil builders. The conclusion, therefore, is that influence was brought to bear on Javanese compositions by Hindu rulers and priests who had themselves no technical knowledge.

INDIA AND THE PACIFIC.—In the *Ceylon Journal of Science*, vol. 1, Pt. 2, Capt. A. M. Hocart marshals in some detail the evidence which, in his view, points to an explanation of the similarities of culture in India and in Fiji as due not to a convergence from a distinct origin, but as being essential elements of a resemblance which could only be due to derivation from a common prototype. The points to which he refers are the cross-cousin system with a common *religious* background as shown in certain ritual practices connected with that relationship, a social organisation with a dichotomous system in each case on Capt. Hocart's interpretation, the relation of the elements within the two caste systems, succession and chieftainship and their attendant rituals and the ceremony of fire walking. Certain divergences are to be explained as due to a simplification that has taken place in Fiji. On the whole, Fijian culture is more archaic and is not to be derived from that of the Vedic literature. It is suggested that this pre-Vedic culture may have been carried to the Pacific by a Mongoloid element of North India, which was partly swamped by the aborigines, partly pushed back into the Himalayas and eastward by western invaders. It is at least certain that everything in south Asia is farther east than it was, and the spread of pre-Vedic culture to the Pacific is merely an episode in a great retreat of people along the southern shores of the Asiatic continent and into the islands.

TRIAL AND ERROR IN THE BEHAVIOUR OF CERTAIN ARTHROPODA.—Prof. W. E. Agar gives an account (*Australian Journ. Exp. Biol. and Medical Science*, Vol. 2, Part 3, 1925) of observations on the behaviour of several arthropods, which were placed in conditions unfavourable to their normal activities, from which in each case there were two apparent avenues of escape—one actually leading to freedom, but the other ending in a cul-de-sac and thus failing to afford relief. In the majority of the experiments the animal was placed in the stem of a Y-shaped passage and when it arrived at the bifurcation had to make a choice between the right or left branches. Experiments with Daphnia involving more than 1400 trials failed to reveal any power on the part of the animal to learn by experience, and a similar finding is recorded for water mites. Young crayfish (Parachæraps) gave very different results, soon learning to avoid the wrong passage and to take the right one, *e.g.* in one experiment in which entry into the wrong passage, besides failing to bring freedom, resulted in an electric shock, the animal took the wrong (left) turn at its first trial but then chose the right passage seven consecutive times. The electrodes were then transferred to the right-hand passage and the animal continued to go into this passage for eight more times, receiving a shock each time, but out of the next twenty-one times made the correct choice nineteen times. The difference of intelligence may perhaps be correlated with the modes of life—the crayfish searches out its food by means of its sense organs, while Daphnia has far less initiative, feeding on microscopic organisms collected by a current of water produced by the movement of certain appendages, and shows no evidence of awareness of other animals or bodies.

HERRING INVESTIGATIONS.—The report for 1924–1925 of the Dove Marine Laboratory, Cullercoats, Northumberland, edited by Prof. A. Meek, contains further investigations on herrings from various localities by Mr. B. Storrow, who, in continuing his work of previous years, finds that the fish hatched in 1920 formed the bulk of the catches from the Shetlands, Firth of Forth, and the north of Scotland. Those caught inside the Forth consisted mainly of much younger fish than those caught south of its entrance; a fact regarded as indicative of a southerly migration for spawning. The author believes that there is again evidence pointing to extended migration from the North Sea and the north-west of Ireland to oceanic waters, and there are possibly similar indications from the south-west of England, but the small number of herrings examined from Milford Haven and St. Ives makes this latter statement very uncertain. He sums up with the following words: "Our work points to migrations from seas to or towards the ocean, and return migrations towards or into seas for spawning." Mrs. Cowan adds data dealing with the size of these same samples. In the faunistic notes the spawning of the lug-worm *Arenicola Marina* is described. White patches were seen in the water towards the end of September 1924, in ripple marks on Cullercoats sands, which proved to be masses of sperms, and the worms were found close to the patches. Most of those examined had already spawned, and on the next day all the worms had disappeared. This probably represented the end of the autumn spawning.

SPECTRAL PHOTOMETRY.—The issue of the *Physikalische Zeitschrift* for December 8 contains a report by Dr. H. B. Dorgelo, of the Scientific Laboratory of the Philips Electric Lamp Works, Eindhoven, Holland, on the recent progress in the methods of determining the intensities of spectral lines by photography. He deals first with the expression of the blackening of a photographic plate as a function of the intensity of the light falling on it and the time of exposure. Then follows a section on the comparison of the intensities of the lines of a narrow group in a photograph by means of photometers and the use of semi-transparent wedges of platinum deposited on quartz as absorbers. For lines far apart it is necessary to compare the photograph of each with that produced by a standard source of light for which the relation between energy emitted, wave-length, and blackening produced is known. Several sources, including the tungsten incandescent lamp, are discussed and the various types of spectro-photometers are considered. Some of the most striking results of observations are given, with references to nearly a hundred papers, mainly of recent date.

THE VELOCITY OF SECONDARY CATHODE RAYS.—The results of an investigation, in which homogeneous cathode rays are made to fall on a blackened metal surface and the secondary cathode rays are retarded by an opposing electrostatic field, are given in a paper by Dr. A. Becker in the November *Annalen der Physik*. It is shown that the secondary electrons are, in general, considerably more numerous than the primary electrons of similar low velocities reflected or diffused backward, so that it is not difficult to determine the manner of emission of the former. The velocity distribution proves to be identical with that of the δ-radiation. The most probable exit velocity, and therefore the absolute value of all the secondary velocities in the cases investigated, is independent of the velocity of the primary rays; there are signs of a decrease at 24 volts, when the limiting velocity for the excitation of secondary radiation is approached. The most probable velocity of the secondary rays is about 2 volts, which agrees with that found for δ-rays. This velocity depends on the nature of the atom in which the secondary ray originates, and it is on the atom that the amount of energy abstracted from the primary corpuscular ray depends. The results fit in perfectly with the views of Lenard on secondary radiation.

THE PRESERVATION OF FRUIT.—B. T. P. Barker and O. Grove discuss a valuable practical application of sulphur dioxide for the preservation of fruit for subsequent use in jam making or as cooked fruit in the home, in the *Journal of Pomology and Horticultural Science* for December. Starting from the problem as to how to preserve pulped fruit put aside at periods of pressure until its conversion into jam is practically convenient, they have reached the conclusion that a better method of preservation of the fruit is to drop it direct into a 0·08-0·1 per cent. solution of sulphur dioxide in an air-tight container. Red fruits in particular lose their colour, but this is largely though not completely restored on boiling, and the skin of gooseberries and currants is toughened as the result of the treatment, but otherwise fruit so treated seems little if at all inferior to fresh fruit for subsequent cooking purposes, and the sulphur dioxide, being volatile, is driven off on boiling. The method therefore seems likely to supersede pulping for the jam manufacturer, whilst in the home, if used with suitable precautions, it may replace the somewhat more troublesome process of bottling in sterile, air-tight containers.

CHEMISTRY IN THE ARTHAŚÂSTRA.—In two recent issues of the *Chemiker Zeitung* (Nos. 134 and 135, 1925) Prof. E. O. von Lippmann deals with those sections of the Arthaśâstra which are of scientific interest. The text of the Arthaśâstra has only comparatively recently come to light; it has been translated into English by Dr. R. Shamasastry, whose edition is that upon which Prof. von Lippmann has worked. The Arthaśâstra is ascribed to an author of the name Kautilya, who lived in the time of King Chandragupta (321-296 B.C.); it deals with problems and methods of government and administration and is largely compiled from more ancient works of a similar character. The latter fact is of particular importance, since it enables us to get an idea of political and administrative conditions in India in a pre-Buddhist age. In the course of the book many facts of scientific interest are mentioned incidentally; these Prof. von Lippmann has gathered together and enriched with annotations. Among the metals gold takes the first place. It is of two kinds—river (alluvial) gold and rock gold. The pure metal is yellow, brilliant, heavy, and very malleable, and on the touchstone gives a characteristic streak. If impure, gold may be purified by fusing it with an appropriate quantity of lead and afterwards treating it with cow-dung and oil. By melting gold with 1 to 15 parts out of 16 of copper, 16 standard alloys can be obtained; these give streaks which can be compared with those of unknown alloys, and thus the composition of the latter may be ascertained. Pure silver is white, shining, and malleable; if it contains impurities, these may be removed by melting the metal with a quarter of its weight of lead. The most important remaining metals are copper (*tâmra*), lead (*sîsa*), tin (*trapu*), iron (*kâlayâsa*), bronze (*kâmsya*), brass (*ârakûta*), *vṛtta* or *vritta* (?), and *vaikṛntaka*. Other substances described are salt (*kshâra*), alum (*sphatika*), borax, blue vitriol (*tîkshna*), and green vitriol (*kâsîsa*). On heating the latter a poisonous vapour with a strong smell is obtained. A number of plant and animal products are also mentioned, together with several poisons (*yôgapâna*). Although fermented liquors are discussed at some length, there is no indication that alcohol was recognised as a distinct substance.

The Physical and Optical Societies' Exhibition.

THE sixteenth annual Exhibition of Electrical, Optical, and other Physical Apparatus held by the Physical Society of London and the Optical Society on January 5, 6, and 7, was marked by a new departure which added greatly to its interest and popularity. In addition to the trade display of scientific apparatus, a number of demonstrations were provided in illustration of typical results of modern research and new or improved laboratory methods, together with lecture experiments and repetitions of famous historical experiments. After the admission of ticket-holders for the usual two days, the Exhibition was thrown open to the general public for a further day, and the available accommodation at the Imperial College of Science and Technology, South Kensington, was fully occupied throughout. There can be no doubt as to the success of the new section, and it is to be hoped that in future years it may be greatly extended. It makes considerable demands on the time of those who take part in it, as the experiments have to be carefully prepared, but public spirit of this kind has never been lacking amongst physicists. Prof. A. O. Rankine must be congratulated on the feat of organisation which he achieved, and mention must be made of the excellent illustrated catalogue, containing brief descriptions of the more important exhibits, which is now printed in a form suitable for inclusion in the bound volumes of the Proceedings of the two Societies.

In the historical section, pride of place must be given to a repetition of some of Newton's fundamental experiments in optics, prepared by Prof. F. J. Cheshire and Mr. B. K. Johnston. Elaborate care was taken to reproduce the original conditions as closely as possible, and an artificial sun was employed, comprising a source of light to which the required angular diameter was imparted by means of a lens system. Sir William Bragg illustrated Faraday's discovery of electromagnetic induction with apparatus which included the coil actually used by Faraday, and Mr. F. E. Smith showed the British Association rotating coil with which Maxwell measured resistance in primary units.

Amongst the more striking lecture experiments may be mentioned those by Mr. G. L. Addenbrooke on electrostatic attraction and by Dr. L. C. Martin on the polarisation of light. In the former, one sparking-ball of a Wimshurst machine is located over a saucerful of castor oil, a few millimetres above the surface. When the machine is operated, a column of oil rises up and adheres to the ball so long as the latter remains charged. In Dr. Martin's experiment, a beam of plane-polarised light is reflected vertically downwards through a sugar solution clouded by particles in suspension. Since the scattered light is seen with maximum intensity in the plane in which it is polarised, and this plane is rotated by the solution at different rates for different colours, the colour of the beam appears to change along its length. A current weigher designed by Mr. F. E. Smith should be of value in getting students interested in the subject of absolute measurements. It comprises a large fixed vertical coil, and a small central horizontal coil which swings about the horizontal diameter of the former. The current to be measured is passed through the two coils in series and the resulting torque is balanced by weights added to a scale pan, which is attached to the moving coil at a suitable distance from its axis.

The research section comprised exhibits by the more important research departments maintained by the Government and by industrial firms. An interesting item in the Admiralty's contribution was the piezo-electric oscillograph. A quartz strip with metal faces contracts longitudinally when the faces are oppositely charged, and this movement may be applied directly to an optical lever; or two strips of quartz may be cemented together in piezo-electric opposition so as to give a bending movement like that of the bimetallic strips used in thermostats. The National Physical Laboratory's exhibits included a Ewing flowmeter (Dr. E. Griffiths and Mr. J. H. Awbery), in which water flowing upwards in a tube containing a steel ball keeps the ball at a height which depends on the rate of flow. When the tube is vertical the ball may either rotate steadily or oscillate from side to side of the tube: two markedly different calibrations are applicable to these two alternative states. Mr. J. Guild showed a colorimeter which enables any mixed colour to be plotted on the colour triangle by means of purely qualitative measurements. The colour is matched against a mixture of a pure red of known wave-length from a filter with monochromatic light selected from a spectrum, the intensities being varied as required but not measured. A similar observation is made with a blue instead of a red filter, and the two wave-lengths of the colours selected from the spectrum determine the required co-ordinates. A useful laboratory method for splitting mica was shown by Mr. F. Harrison Glew. Two pieces of adhesive tape are attached to the faces of a mica sheet and pulled apart. This operation starts a split which can be extended with a piece of cardboard, and by repeating the process a sufficient number of times, sheets giving interference colours can be obtained without difficulty

A discourse was delivered each evening during the Exhibition. At the first, on "The Search for Ultra-Microscopic Organisms," by Mr. J. E. Barnard, the attendance was so great that a number of persons were unable to obtain admission, but the speaker's good nature and endurance proved equal to an immediate repetition of the discourse for their benefit. Mr. Barnard explained that the resolution obtainable with a microscope is limited on one hand by the formation of diffraction patterns if the wave-length be too long, and on the other by the opacity of the lens-material if the wave-length be too short. The organisms which are to be photographed have to be grown on a nutritive layer as thin as 0·2μ, in order to avoid opacity, and the wave-length varies from 220$\mu\mu$ upwards, different wave-lengths giving different pictures, owing to differential absorption in the tissues of the object. The microscope combines two lens systems which are appropriate respectively to visible and to ultra-violet radiation, have one quartz lens in common, and are focussed by means of the same mechanism. The latter is calibrated, so that when focussing has been accomplished for visible light of known wave-length, the instrument can at once be set, with the aid of the calibration, for the required ultra-violet illumination. The visible light is used with dark-ground illumination, the ultra-violet with a camera. The organisms of malignant growths are found to be so small that the ratio of their surface tension to their mass is too great to permit of reproduction by central fission, and young individuals make their appearance as a series of thickenings in the cell wall of the parent, which ultimately remain attached thereto only by a spiral filament.

Prof. A. F. C. Pollard's discourse dealt with "The Mechanical Design of Instruments." He claimed that a scientific instrument must be looked upon as a mechanism, for transmitting motion rather than power, and that it must be designed in strict accordance with kinematic principles. The design of a pair or coupling is governed by the principle that a part is fixed in position when its six possible degrees of freedom have all been constrained by the location of six of its points upon six planes. Any further constraint, such as exists in most instruments, is redundant and involves the accurate fitting together of parts, which is far more difficult and costly than the accurate geometrical shaping of parts taken by themselves: the latter process only is required when redundant constraints are avoided, and at the same time the effects of wear due to imperfect fit are eliminated. The principle was illustrated by reference to actual instruments in which such mechanisms as the hole, slot, and plane of Lord Kelvin and the rectangular knife-edge arrangement of Sir Horace Darwin have been employed. As regards the links or rigid parts of an instrument, their design must be governed by a knowledge of what is practicable in a workshop: for example, castings must not have thin parts integral with adjacent thick parts, and holes must not be located so that in drilling them the tool has to work through a face to which it is inclined.

The discourse by Major W. S. Tucker on "Electrical Listening" was illustrated by a number of demonstrations of the properties of microphones, particularly of the tuned microphones associated with his name and used in military sound-ranging. These instruments, in which a very fine hot wire forming one arm of a Wheatstone bridge is arranged as a mesh across the mouth of a Helmholtz resonator, have been given a much enhanced selective sensibility for low frequency disturbances by closely coupling the main resonator with a second resonator of equal pitch. Perhaps the most striking experiment was that in which the speed of a siren was gradually decreased. The resonant microphone in combination with a vibration galvanometer gave a strongly marked indication as each harmonic of the siren passed through the selected pitch. The speaker also showed records of the notes emitted by lightships, taken at a distance of 9 miles, and of thunderclaps, the indicated duration of the latter being much longer than the duration apparent to the ear.

The trade exhibits included a large number of beautiful instruments, many of them new or improved, but space is available for the description of only very few of these. A fuller account has been published in the illustrated catalogue of the Exhibition The attractive exhibit of Messrs. Adam Hilger, Ltd., included a demonstration with one of their piezo-electric resonators, which are used in standardising wireless wave-lengths. The crystal employed has a mechanical resonance frequency comparable with wireless frequencies, and when it is connected in a suitable circuit, the marked oscillatory piezo-electric E.M.F. which is set up at the fundamental and harmonics of the mechanical resonance enables it to be used for standardising wave-meters, the minimum wave-length being 20 metres. The most interesting feature of the stand occupied by the Cambridge Instrument Co., Ltd., was an improved design of Duddell oscillograph. This instrument is now fully portable, gives direct vision and three simultaneous records on 50 cm. or shorter strips of ordinary photographic paper, permits of any combination of electromagnetic and electrostatic vibrators, and employs a filament lamp. A novelty in dial recorders is the use of carbon paper by the Foster Instrument Co., the stylus making its impression from behind so as to press the carbon paper upon the semi-transparent record paper against the glass face of the instrument. A new method for preventing the bursting, under excess pressures, of the expanding metal chambers used in barometers and the like is embodied in a thermostat by Negretti and Zambra: in this case the chamber is enclosed in a gas-tight chest and the pressure acts upon it from without. Several ingenious features are also to be found in the Ashdown rotoscope (Elliott Brothers (London), Ltd.) for observing periodic movements such as those of machine parts or even of a flying insect. The stroboscopic shutter is a rotating disc driven by clockwork through a five-speed gear, intermediate speeds being adjusted by means of a governor control. The total range of speeds is from 300 to 20,000 r.p.m. The motor can be started or stopped by turning or holding its shaft with the hand, the difference between static and dynamic friction being utilised to this end in the design; the instrument can be held in one hand when in use.

Much interest was shown in a working example of the Admiralty's apparatus for sounding depths by timing echoes, which is being manufactured by Messrs. Henry Hughes and Son, Ltd. The principle employed is that in which a signal note is emitted at regular intervals and a normally deaf telephone is momentarily rendered sensitive after the lapse of an adjustable interval. The length of this interval when the adjustment is such that the echo can be caught by the telephone measures the depth of the sea. It is believed that the use of a rapidly damped signal note, in combination with other detail improvements, has yielded a fool-proof apparatus. Messrs. C. F. Casella and Co., Ltd., exhibited a surveying instrument designed by Dr. J. S. Owens, for recording the inclination of a bore hole in elevation and azimuth. The instrument contains a complete photographic chronograph, a magnetic compass mounted in gimbals, and a clinometer, and it can be inserted complete into a 2-inch bore hole. It should serve to prevent the distress felt by engineers when a borer, after much apparently successful labour, is found to have behaved like a boomerang. Telephones for the relief of deaf persons have been in use for a long time, but have often proved unsatisfactory owing to the variety in types of deafness. To overcome this difficulty Mr. W. H. Pettifor has designed a test instrument which enables prescriptions to be written for individual patients, analogous to opticians' prescriptions; it is found that each patient requires a combination of microphone and telephone having a particular frequency-characteristic and sensitivity.

In all, some seventy-two firms exhibited It is, naturally, impossible in the space available in NATURE to describe more than a few of the many important instruments which went to make up this impressive display.

Regional Scientific Work.

THOSE interested in the publications of the local scientific societies in Great Britain will have noticed that after the falling off in the printing of memoirs which occurred during the War, there has been a healthy revival. Notwithstanding the enormous increase in the cost of printing and binding, many of the scientific societies have reached the pre-Wa standard of their reports, and in some cases have even exceeded that. A perusal of the enormou number of reports and transactions recently issued shows that much more discrimination is now being taken in the publication of papers by the scientific societies. Whether as a result of the Conference of Delegates at the British Association, or the various criticisms and suggestions appearing in NATURE and other journals, those responsible for the production of publications of local interest are certainly adding considerably to the value of these transactions by confining the contents as near as possible to the district covered by the societies' activities.

Some societies are sufficiently strong financially, and in scientific workers, to continue printing their publications independently; others, wisely, have amalgamated, and by thorough organisation have produced a joint publication containing the reports of the various committees and sections, which is of permanent value. As an example of the former, we have recently received the *Proceedings and Transactions of the Croydon Natural History and Scientific Society* (Vol 9, Part 4. Price 5*s*. net). This covers the period February 1923 to January 1925 It includes reprints of the various monthly circulars which the Society has issued containing particulars of the meetings and excursions, with summaries of the work of the sections of archæology, botany, geology, microscopy, physics and chemistry, regional survey, and sociology and psychology. There are the two presidential addresses of Mr. G. M. Davies, one dealing with geology and lines of transport in the Croydon district, and the other with the sea in Surrey, both being of particular value to Croydon naturalists.

An exceedingly valuable part of the publication is that devoted to the meteorological reports for 1923 and 1924, by Mr. F. Campbell Bayard. The cost of compiling and printing these, both from the point of view of time and money, must have been tremendous, and we are not surprised to learn from the Council's report that for both reasons the printing of these reports will not be continued, though full particulars will be sent to the British Rainfall Organisation. Mr. Campbell Bayard is to be congratulated on having accomplished this onerous work for thirty-seven years, and the Society has done well to elect him an honorary member. As a frontispiece to the volume is a really beautiful protrait of the late Mr. William Whitaker, who was one of the most familiar figures at the meetings of many scientific societies, and took a prominent part in Croydon affairs.

The *South-Eastern Naturalist* comes under the second category, and this Society and its organisation is founded upon that of the Yorkshire Naturalists' Union, the pioneer scientific union in the British Islands The South-Eastern Union's publication, the *South-Eastern Naturalist* for 1925 (lxxxii + 107 pp. Price 5*s*. net), contains a record of the Folkestone congress. As frontispiece is the inevitable "group," which always impresses us as containing portraits of a greater proportion of old people than can be found in any other group of this character! Here the reports and proceedings of the various sections and committees, records of the congress, the obituary notices, etc., are thoroughly well done. The presidential address of Sir John Russell, entitled "The Place of Science in Rural Life," is printed. E. C. Stuart Baker refers to evolution and field naturalists; A Steven Corbet writes on the marsh-warbler in Britain, with a bibliography; D. Ward Cutler describes life in a garden soil, Prof. A G. Tansley writes on vegetation of the southern English Chalk; Miss Lillian Lyle on seaweeds of Folkestone—how they grow; A. L. Leach on geological elements in the scenery of south-eastern England (with many interesting illustrations); C. J. Gilbert on the genesis of the Straits of Dover and the creation of Romney Marsh; G. L. Pepler on regional survey as a preliminary to town planning; E A. Robins and J. H. Pledge on making photographic prints for regional survey; E. A. Martin on problems in anthropology; A. H. Reade on Barfrestone Church; and A G. Davies on notes on new geological sections in the London district.

In his paper on problems in anthropology, Mr. Martin says: "When we find what looks like an implement and we do not quite know what were its uses, we say it was some kind of scraper. Scrapers were of all ages in human times. Eoliths would make good scrapers Has any one ever seen a dog or cat take a stone to scrape himself with it? Here again is evidence of the growth of self-consciousness, when man wished to lead a cleanly life. I take it that he did not use his scrapers only for cleaning the skins of animals he had captured and which he wished to utilise as clothing. He would use them to clean himself," and so on.

T. S

Annual Meeting of the Science Masters' Association.

THE twenty-sixth annual meeting of the Science Masters' Association was held on January 5, 6, and 7 at the Household and Social Science Department of King's College for Women, by kind permission of the authorities. There was a large attendance, and the meeting was in every way very successful. After the opening dinner in the refectory of the College, the presidential address was delivered by the Bishop of Birmingham, the Right Rev. Dr. C. W. Barnes.

Dr. Barnes directed attention to the effect of the progress of science upon religious belief, and said that science is now, and must continue to be, an essential element in human culture. It not only gives us a picture of the universe, in which all man's spiritual faculties must find a place, but also helps us the better to understand ourselves and our fellow men. It will, in due course, enable mankind to strengthen its social fabric, to which end it is desirable to check the multiplication of degenerate racial stock. The principles of science and scientific method must be applied universally, even to the phenomena of the religious consciousness. True religion will not suffer if the scientific temper prevails. The absurd contention that if man were a developed ape there could be nothing in him but what the ape possessed is almost forgotten. Using Lloyd Morgan's phrase, Dr. Barnes pointed out that evolution is characterised by the "emergence" of new degrees of reality. Science, he said, can help human progress by destroying false realisations of religious experience and can purify religion by divesting it of accretions which linger from pre-scientific times. It has already banished fear from the minds of educated men by giving them a satisfactory understanding of natural phenomena. It has also banished the gods; the universe is a unity and not subject to the control of super-personalities. Science is built on the postulate of the uniformity of Nature, and its triumphs show that this postulate is sound.

Science has banished the gods: has it banished God? Dr. Barnes is of opinion that, in effect, it has done this if pantheism or naturalism are the interpretation of the universe to which it leads; but no such interpretation is necessary or even probable. That the universe is a self-acting machine is an incredible assumption, and renders the emergence of man's spiritual faculties entirely inexplicable. If, on the other hand, we identify God with the universe, good and evil are alike divine, our moral intuitions are meaningless. Goodness, beauty, and truth must of necessity find a place in our interpretation of the universe, so naturalism and pantheism do not adequately explain the cosmos to which man belongs. Science, then, does not banish God, neither does it banish the conception of the kingdom of God as formulated by the Founder of Christianity. Science, however, can answer none of the ultimate questions. They are not her province. But though her range is limited, within that range she leads us from error to truth, from fantasy to fact. On the truth which science has revealed and is still revealing we have built the new humanism of this age. The religious outlook, in which modern science has been cradled, will not only be able to co-exist with the new humanism, but will derive from it an added power of appeal to the intellect of man.

A vote of thanks to the president was ably moved by a very old and valued friend of the Association, Prof. A. Smithells, and was seconded in a felicitous speech by Prof. Percy Nunn, it was carried with acclamation.

Thursday's programme included a lecture by Prof. Leonard Hill upon "Sunshine, Open Air, and Health," and a discussion upon laboratory assistants, laboratory management, and school exhibitions. On the question of laboratory assistants in schools, a matter which affects most members of the Association very closely, it is felt that some definite scheme for the provision, training, and payment of such men is urgently required, and the committee was requested to make a special inquiry into the subject.

At the business meeting, the momentous decision was taken to institute the formation of local branches. The reasons which led the Association to undertake this step were chiefly two: (*a*) to get into closer contact with local universities, in order to deal more easily with the numerous problems which arise in the teaching of science in schools and in the correlation of school courses with university requirements, etc.; and (*b*) to promote the social side of the Association. Arguments against the formation of branches were put forward, but the weight of the meeting was strongly in favour of the idea. We are pleased to note that according to the rules drafted for the regulation of branches, non-members who are interested in the objects of the Association may, at the discretion of any branch committee, be invited as guests to meetings of the branch other than a business meeting. This affords opportunity for closer co-operation between the Science Masters' Association and the Association of Women Science Teachers, which, in view of the fact that both associations have the same aims and are faced by the same, or very similar, problems, seems very desirable.

Additional features of the meeting were lectures and demonstrations by Prof. B. J. Collingwood, Dr. C. S. Myers, Rev. F. Aveling, Miss W. Spielman and others, while visits were arranged to the National Physical Laboratory and the General Electric Company's Laboratories. There was also an excellent exhibition of scientific apparatus, and of chemicals, by the leading manufacturing firms, while the publishers' show in the Library was a source of great interest, judging from the crowds of members always present there. The table reserved for books written by members of the Association was striking testimony to the literary activity of science masters, and the members' exhibits of apparatus bore witness to no little ingenuity. It is not too much to say that, of all the numerous associations of teachers in Great Britain, the Science Masters' Association is one of the keenest and most vigorous.

The meeting in January 1927 is to be held at Oxford, an announcement which was received with enthusiasm by the members, who retain a lively recollection of the success of the last meeting there. The new president is Brig.-Gen. Harold Hartley, and the chairman for 1926 Mr. E. J. Holmyard (Clifton College).

University and Educational Intelligence.

PROVISIONAL announcements are now available of a number of free public lectures and short courses by eminent men of science and other scholars, to be given at various colleges of the University of London. Lectures at King's College include three by Prof. A. S. Eddington on the constitution and evolution of the stars, commencing February 22; two by Prof. R. Ruggles Gates on vegetation on the Amazon, commencing February 19; and five by Dr. F. A. P. Aveling on the human will, commencing January 18. At University College, Prof. W. H. Lang is to deliver three lectures on the morphology of the Vascular Cryptogams, commencing March 1, at 5.15 P.M.; Dr. C. M. Ariens Kappers, four on the evolution of the nervous system, commencing March 9; Mr. M. H. Krishna, eight on Indian archæology and anthropology, commencing January 18; Miss M. A. Murray, two on Egyptian architecture and primitive cults in ancient Egypt, commencing January 26, Dr. R. W. Lunt, six on the chemistry of ionisation by collision, commencing February 1; Dr. E. G. Richardson, three on the acoustics of buildings, commencing January 19; and Dr. Geoffrey Martin, one lecture on the theory of fine grinding, on February 12, at 5 P.M. Lectures at the London School of Economics include one by Dr. B. Malinowski on the aims of social anthropology, on February 18, at 5 P.M. Except where otherwise stated, the lectures begin at 5.30 P.M.

ALL universities in Ecuador were closed by a Government decree last August. Commenting on this event, the secretary to the United States Legation, Quito, remarks in an article published in the November issue of *School Life*, that for many years past the degrees of doctor of law and doctor of medicine have been too easy of attainment. To graduate in one of these faculties had come to be looked upon as the best badge of "respectability," and the country is flooded with doctors and lawyers, most of whom are unable to earn a living at their profession, and many of whom are but poorly equipped for it. Similar drastic methods of restricting the recruitment for the legal profession have been adopted in Bolivia, where, however, those who have actually begun their professional courses of study are to be permitted to complete them, after which the law faculties are to be closed down. The editor of *School Life* asks whether it is not time to apply some restriction to the present scale of output of lawyers in the United States, where students of law are more than twice as numerous as students of medicine. Only 46 of the 160 law schools require for the law degree so much as five years of study after the completion of the secondary school course, and only one-fifth of the whole number of law students were in those 46 schools. The other four-fifths were in schools which conferred the degree for four years of study at most. It is suggested that the levelling-up process that has in recent years been applied to medical studies should be now applied to the study of law.

Contemporary Birthdays.

January 15, 1875. Dr. T. G. Longstaff, F.R.G.S.
January 17, 1851. Sir James Cantlie, K.B.E
January 18, 1868. Sir Leonard Rogers, C.I.E., F.R.S.
January 21, 1855. Sir Henry B. Jackson, G.C.B., F.R.S.

Dr. T. G. LONGSTAFF, traveller in many regions, and Himalayan mountaineer, was educated at Eton and Christ Church, Oxford. His medical training was pursued at St Thomas's Hospital, London. We quote the following from his paper, "A Mountaineering Expedition to the Himalaya of Garhwal," read before the Royal Geographical Society in January 1908: "I first visited these mountains on my return journey from Tibet in 1905. With my colleagues we hoped to celebrate the jubilee of the Alpine Club by attempting the ascent of Everest, or at least the exploration of its unknown glaciers. We were peremptorily forbidden by the Home Government to enter Tibet."

Sir JAMES CANTLIE comes of Banffshire stock. Educated at Milne's Institution, Fochabers, he graduated at the University of Aberdeen, and entering Charing Cross Hospital Medical School in 1871, he afterwards became a lecturer there. Successive students did not fail to carry on the cheery pseudonym of "Jimmy." An ardent traveller, he has been practically all over the world. He visited China in 1887, and was, from 1889 to 1896, Dean of the College of Medicine for Chinese. Sir James is a Knight of Grace of the Order of St. John of Jerusalem. He has written much on surgical science and public health, and is widely known as an exponent of methods of physical training and bodily efficiency.

Sir LEONARD ROGERS, Lieut-Col. I.M.S. (retired), was educated at Plymouth College. Entering St. Mary's Hospital Medical School, he became F.R.C.S., 1893, M.D. (Lond.), 1897. Physician and lecturer at the London School of Tropical Medicine, he was, before retirement from the Indian Medical Service, professor of pathology at Calcutta Medical College, and Government Bacteriologist. Sir Leonard is a Fothergillian gold medallist of the Medical Society of London, and has received the Mary Kingsley medal of the African Society for researches in tropical medicine.

Admiral of the Fleet Sir HENRY B. JACKSON, Grand Officer of the Legion of Honour, was born at Barnsley. Entering the Navy in 1868, he attained his captaincy in 1896, was controller of the Navy, 1905–8, and commanded the Sixth Cruiser Squadron, Mediterranean, 1908–10. Identified with the initial practical use of Hertzian waves for wireless communication between H.M. ships, it may be recalled that on May 15, 1902, Capt. Jackson read a paper before the Royal Society entitled "On some Phenomena affecting the Transmission of Electric Waves over the Surface of the Sea." He stated that in 1895 he began systematic experiments with the view of utilising the effect of Hertzian waves on imperfect electrical contacts for naval signalling purposes. It is interesting to note that on June 12 following, Mr. Marconi also read two papers, one, "Note on a Magnetic Detector of Electric Waves which can be employed as a Receiver for Space Telegraphy"; the other, "On the Effect of Daylight upon the Propagation of Electromagnetic Impulses over Long Distances."

Early Science at Oxford.

January 18, 1683–4. After the reading of ye Minutes, a letter from Mr. Aston to Dr. Plot, was read; which tells us, that some of ye Royall Society are of opinion, that ye Porphyry Pillars, mentioned in an abstract of Mr. John Greaves MS. (lately communicated to us by Dr. Smith, and transmitted to ye Royall Society) were not brought from Mount Sina, as Mr. Greaves supposes, but dug in Ægypt; wherefore it was ordered, that Dr. Huntingdon should be consulted, as to this matter.

A letter from Dr Hatly of Maidstone concerning some Petrifications found in Kent, was read; He endeavors to prove, that these Petrifications are *Lapides sui generis*, and not made in *animal molds*.

The Ore of ye *Ferrum Noricum** (part of that generous present, with which ye learned Martin Lister Esq has lately oblidged our University) was seen to apply to ye magnet; as also ye common black writeing sand; neither of which can well be supposed to have undergone ye fire. It was then quæried, whether our common ores will not apply, if powdered? Dr. Plot was pleased to take on him ye trouble of trying it.

1686–7. A letter from Mr. Peck of Mayfeild in Sussex, was read. It gave a large account of the man sick of a Feaver mentioned in the Minutes of Dec. the 7th. with some other cases in Physic very remarkable. Mr. President's letter to Mr. Halley concerning the cause of the Trade-winds, was read.

January 19, 1685–6. A letter from Mr. Molyneux, concerning some observations on Mr. Hevelius's *Annus Climactericus* and on his account of ye Lunar Ecclipse on ye 30th of Nov: 1685—A letter from Mr. Brown to Mr Aston concerning ye Liver as appearing glandulose in a morbid body opened at St. Thomas's Hospitall, London; A letter, subscribed W. Tenon, concerning Dr. Papin's way of raising water, were all communicated and read.

January 20, 1684–5. A foot cubic measure, made by order of ye Society was presented by Mr. Caswell, and Mr. Walker. A catalogue of experiments to be tried with this measure, was drawn up, and put into Mr. Caswel's hands; and a pair of fine scales were proposed to be provided.

A letter from Dr. Middleton, Provost of Kings College, Aberdeen, gives us hopes, of what we have so long, and so earnestly desired, viz a correspondence with Scotland. The Doctor desiring some account of ye manner of our proceedings, ye Secretary is commanded to prepare a transcript of ye Orders, and ye latest Minutes, to be sent him.

A detailed Answer was given to ye 39th Quere of Sir William Petty's Catalogue of Experiments to be tried, (which Q. runs thus, viz: How many shoes of a certain size, a shoemaker can make up in a time given?). It was Affirmed that of ye five first sizes of *children's shoes*, called *Children's pumps*, 12 pair may be made, by a good workman, in one day; that of children's *Eights*, 4 pair are an ordinary days work; and that of Women or Men's *Sixes*, 3 shoes, or 2 pair, are usually a Day's work.

Mr. Musgrave affirmed that 80 lb: of Wedgbury pit coal, kindled at several times, with 4¼ lb of Charcoal, gave a little above ¼ of a peck of Ashes, which weighed 4¼ lb. avoird', beside which about a pound of coal was left unburnt in ye grate: so that a pound of this sort of coal, well burnt, does not yeild an ounce of Ashes. A discourse was presented by Mr. Walker, proving from experiment, that ye longer ye wheels of a coach are, (cæteris paribus) ye more easily they may be drawn over a stone, or such like obstacle, that lies in ye way.

Societies and Academies.

LONDON.

Optical Society, December 10.—Col. H. S. L. **Winterbotham**: General principles of photographic surveying. A brief outline is given of the development of photogrammetry from terrestrial and aerial positions, and an indication of some of the points to be considered in the design of instruments required by the photogrammetric surveyor in Britain.—Lieut.-Col. W. N **MacLeod**: Perspective conditions of photogrammetry. The perspective conditions which must be satisfied in aerial survey work are discussed and the methods of reconstructing these conditions from the photographs obtained are described. Attention is directed to the desirability of designing new apparatus, with which to carry out the necessary reconstruction with the requisite accuracy.—Lieut. M. **Hotine**: Some precision problems in air survey. The various factors upon which accuracy in air survey measurements depends are described and suggestions are made as to some of the conditions which should be fulfilled in apparatus employed for such measurements.

The Physical Society, December 11.—E. A. **Owen** and G. D. **Preston**: The effect of rolling on the crystal structure of aluminium. Sheets of aluminium have been examined by the ionisation spectrometer and by photographic methods. When a cast specimen of aluminium containing a number of large crystals oriented at random throughout the body of the material is rolled, the crystals break up into a large number of minute crystals. As the thickness of the material is progressively diminished, the small crystals tend to take up a definite orientation, each crystal having a cube diagonal in the direction of rolling and a (211) plane in the plane of rolling. Two sets of crystals exist in the material after rolling, one set being the optical image of the other in the plane of rolling. The ionisation spectrometer indicates that the type of the space lattice remains unaltered, and that the parameter of the material in the severely worked condition does not differ from that of the annealed material by more than 0·5 per cent.—R. S. **Burdon**: The spreading of one liquid on the surface of another. Purest "conductivity" water in the presence of air spreads very slowly on a clean mercury surface; the spreading is greatly accelerated by traces of acid in solution, and totally inhibited by traces of alkali. All the neutral salts tested, even chlorides of mercury and silver, produce rapid spreading. The concentration of the solution controls the rate of spreading. All acid solutions tested spread rapidly, probably reacting chemically with the mercury. One part of hydrochloric acid in ten million of water definitely accelerates spreading. A drop of very dilute acid spreads rapidly to cover a definite area and stops, any further spreading being as slow as that of water. The area covered during the rapid stage is proportional to the number of acid molecules present, and is larger than would be expected if a monomolecular layer of the appropriate salt were formed on the mercury surface. Electrostatic fields up to 4,000 volts/cm. applied perpendicular to the surface produce no visible results. Placing a platinum wire from one terminal of a battery in the mercury and from the other terminal in the drop, and applying small voltages, causes spreading even in alkalis if the mercury be positive, and prevents spreading even in dilute acids if the mercury be negative. Photographs show that the spreading drop is preceded by a well-defined ridge.—J. T. **Combridge**: On the advance of the perihelion of mercury. Attention is directed to the infinite possibilities of obtaining the Einstein equation for the orbit of a planet by using Newtonian mechanics with an extended potential function. Observational tests being equally satisfied, Einstein's theory is to be preferred on account of its extensive unity and the spontaneity of its results.

Linnean Society, January 7.—Eric Marsden **Jones**: On the fertilisation of *Primula vulgaris* Huds. Observations were made by day and night in a wood at Potterne in Wiltshire in order to ascertain with the greatest degree of accuracy the part that day- and night-flying insects might play in the pollination of this plant. During day observations, five important species of insects were seen pollinating frequently. During night observations the only visitors seen were *Meligethes erythropus*, *Tachyporus salutus*, and *Forficula auricularia*, which are of no value from a pollinating point of view. Two blocks of 50 plants each were covered alternately day and night as a control. The patch from which insects were excluded at night produced 343 capsules, while the one exposed by night, and from which day-flying insects were excluded, produced only 5, for which there is an explanation. Six plants covered entirely day and night were absolutely sterile. It seems, therefore, that diurnal insects pollinate efficiently, and that nocturnal Lepidoptera play no part whatever in the pollination of *Primula vulgaris*.—M. A. C. **Hinton**: Persistent growth in the water vole and old age in the wart hog. A contribution to the growth and death discussion. The ancestors of the voles possessed tuberculate teeth of limited growth adapted for bruising and crushing the relatively soft and succulent substances composing a mixed diet. The voles have acquired the power of subsisting upon coarse, tough, vegetable substances, and this has led to modifications, particularly in the molar teeth. These have become tall-crowned, prismatic structures adapted for slicing and shearing the food; and the dentinal pulps and enamel organs of the teeth appear to remain active throughout life. The water vole (*Arvicola amphibius*) is remarkable in another way: In the oldest individual known, not only were the molar teeth actively growing at the moment of death but the skeletal development was still incomplete It would seem that the water vole and some of its relations never stop growing. The last molar and the enormous canines of the wart hog have been described as being persistently growing teeth. Recently acquired material shows that, if the wart hog lives long enough, these teeth finish growing, develop roots, and wear out, so that in due course the animal becomes senile and dies. Probably if we could secretly defend a water vole from accident indefinitely while exposing it to normal Microtine existence, its growth would cease, and it would proceed to old age and death like a normal mammal.

SYDNEY.

Linnean Society of New South Wales, November 25.—A. **Philpott**: The labial palpi of *Trichophysetis cretacea* and *Argyria amoenalis*. Modifications of the palpi occur in males although the females are quite normal.—John **Mitchell**: Descriptions of new species of Leaia. The genus is confined to rocks of Carboniferous and Permian ages; and consequently its occurrence, in great variety, in the Newcastle Coal Measures forms one of the most convincing proofs of the Permian age of these measures. Thirteen species are described as new.—H. M. **Hale**: The development of two Australian sponge-crabs. Two marine crabs, an oxyrhynch (*Paranaxia serpulifer*) and a dromiid (*Petalomera lateralis*), do not pass through the usual free-swimming larval stages, the young leaving the female in the adult form. In the latter, at least two advanced juvenile stages are spent in the brood-pouch of the female. The metamorphosis is almost completely suppressed in another sponge-crab (*Cryptodromia octodentata*) and a third (*Platydromia thomsoni*) probably has a "direct" development.—Ida A. **Brown**: Geology of the Milton District. Within a radius of ten miles of Milton there are a number of outcrops of igneous rocks. An account is given of the albitisation and of the history of the intrusions.—I. M. **Mackerras**: The Nemestrinidæ (Diptera) of the Australasian region. Of the 40 specific names hitherto proposed, 22 are considered as valid and 2 cannot be placed; 1 genus, 16 species, 3 subspecies and 1 variety are described as new.—E. W. **Ferguson**: Description of a new species of Mycetophilidæ (Diptera) with luminous larvæ. A new species of Arachnocampa is described from Ida Bay Caves, Tasmania.—L. **Harrison** and Hazel C. **Weekes**: On the occurrence of placentation in the scincid lizard, *Lygosoma entrecasteauxi*. The occurrence of true placentation in two not very closely related scincid lizards, Lygosoma and Chalcides, in Australia and Europe respectively, indicates that the allantoplacenta is a functional adaptation which may have arisen independently many times in evolution, and upon the mere occurrence of which phylogenetic statements cannot justifiably be based. A consideration of reptilian placentation suggests three stages, chorioplacenta, omphaloplacenta and allantoplacenta arising in that serial order, both in ontogeny and phylogeny.—W. J. **Phillipps** and F. J. T. **Grigg**: The salinity of inshore oceanic waters of Australasia in relation to fishes.

Official Publications Received.

The Indian Forest Records, Vol. 11, Part 10 (Economy Series). Notes on the Antiseptic Treatment of Assam Timbers for Railway Sleepers. By J. H. Warr, assisted by S. Kamesam. Pp. iv+106. (Calcutta: Government of India Central Publication Branch.) 1.14 rupees, 2s. 3d.

Meteorological Office: Air Ministry. Advisory Committee on Atmospheric Pollution: Report on Observations in the Year ending March 31st, 1925. Forming the Eleventh Report of the Committee for the Investigation of Atmospheric Pollution. (M.O. 280.) Pp. 46. (London: H.M. Stationery Office.) 5s. 6d. net.

Madras Fisheries Department. The Fishing Methods of the Madras Presidency. By James Hornell. Part 1: The Coromandel Coast. (Report No. 2 of 1924, Madras Fisheries Bulletin, Vol. 18.) Pp. 59-110. (Madras: Government Press.) 12 annas.

Society for the Provision of Birth Control Clinics. Annual Report 1924–1925. Pp. 14. (London: 153a East Street, S.E.17.)

Dove Marine Laboratory, Cullercoats, Northumberland. Report for the Year ending June 30th, 1925. (New Series 14.) Edited by Prof. Alexander Meek. Pp. 58. (Cullercoats.)

Leeds University. Report to the Worshipful Company of Clothworkers of the City of London of the Advisory Committee on the Departments of Textile Industries and Colour Chemistry and Dyeing, during the Session 1924–25. Pp 16. (Leeds.)

University of California Publications in American Archaeology and Ethnology. Vol. 17, No. 7: Archaic Culture Horizons in the Valley of Mexico. By A. L. Kroeber. Pp 373-408+1 plate. (Berkeley, Calif.: University of California Press.) 45 cents.

Smithsonian Institution: United States National Museum. Contributions from the United States National Herbarium. Diary of Societies and Public Lectures.

SATURDAY, January 16.

Scottish Junior Gas Association (at Royal Technical College, Glasgow), at 7.—D. Garrie: Paper.

MONDAY, January 18.

Royal Geographical Society (at Lowther Lodge), at 5.—The New Photo-Theodolite of Mr. A. Wild (Report and Discussion).

Royal College of Surgeons of England, at 5.—Sir Arthur Keith: Fossil Remains of Ape and Man: (1) The Anatomical Characters of the Galilee Skull.

Faraday Society (at Chemical Society), at 5.30.—B. B. Banerji: The Electrode Capacity and Resistance of Electrolytes for a Wide Range of Frequencies.—J. A. V. Butler, W. E. Hugh, and D. H. Hey: The Effect of the Electrode Material on Oxidation Potentials.—R. H. W. Maddison: The Electromotive Behaviour of Cupric Oxide.—A. Highfield: The Colloidal Properties of Nitrocellulose Sols in Mixed Solvents.—E. P. Perman and T. Lovett: Vapour Pressure and Heat of Dilution of Aqueous Solutions. Part I. (*a*) Vapour Pressure of Aqueous Solutions of Urea; (*b*) Heat of Dilution of Aqueous Solutions of Urea.—W. Taylor: A Note on Kinetic Activation as a Factor in Gas Reactions.

Institution of Automobile Engineers (Loughborough Graduates' Meeting) (at the College, Loughborough), at 7.—C. Legge: Sparking Plugs.

Institution of Electrical Engineers (Teesside Sub-Centre) (at Cleveland Technical Institute, Middlesbrough), at 7.15.—E. E. Dunn, W. S. Ramsdale, and others: Informal Discussion on The Isolation, Location, and Repairs of Faults.

Junior Institution of Engineers (North-Western Section) (at 16 St. Mary's Parsonage, Manchester), at 7.15.—W. D. Adamson: The Importance of the Selling Aspect of Production Planning.

Institution of Automobile Engineers (Scottish Centre) (at Royal Technical College, Glasgow), at 7.30.—J. D. Parkes: Logic applied to Failures.

Institution of Electrical Engineers (Mersey and North Wales (Liverpool) Centre) (at Liverpool University), at 7.30.—A. P. Trotter: Illumination and Light (Faraday Lecture).

Royal Institute of British Architects, at 8.—Award of Prizes and Studentships.

Royal Society of Arts, at 8.—H. P. Shapland: The Decoration of Furniture (Cantor Lectures) (1).

Aristotelian Society (at University of London Club), at 8.—Dr. F. W. Thomas: Conventional Existence.

Chemical Industry Club.

Institute of Chemistry (Manchester and District Section) (at Manchester).—C. Hollins and others: Discussion: Chemical Nomenclature.

TUESDAY, January 19.

Royal Anthropological Institute (Edinburgh and the Lothians Branch) (at Synod Hall, Edinburgh), at 5.—Dr. J. Ritchie: The Arrival of Man in Scotland.

Royal Institution of Great Britain, at 5.15.—Prof. J. A. Crowther: X-rays and Living Matter (1).

Royal Statistical Society (at Royal Society of Arts), at 5.15.—R. J. Thompson: The Productivity of British and Danish Farming.

Royal Society of Medicine, at 5.30.—General Meeting.

Mineralogical Society (at Geological Society), at 5.30.—Dr. C. E. Tilley: Some Mineralogical Transformations in Crystalline Schists.—Dr. A. Brammall: Gold and Silver in the Dartmoor Granite.—A. H. Hallimond: On the Chemical Classification of the Mica Group. II. The Basic Micas.—G. Greenwood: The Construction and Use of an X-ray Goniometer.

Institute of Marine Engineers, at 6.30.—W. Blane: Poetry and the Engineer.

Institution of Electrical Engineers (East Midland Sub-Centre) (at Loughborough College), at 6.45.—A. B. Mallison: Justifiable Small Power Plants.

Royal Photographic Society of Great Britain (Scientific and Technical Group), at 7.—W. D. Baldsiefen, F. F. Renwick, and Dr. V. B. Sease: Silver Iodide in Photographic Emulsions.

Institution of Automobile Engineers (Coventry Graduates' Meeting) (at Coventry), at 7.15.—H. W. Sisman: The Straight Eight Engine.

Society of Chemical Industry (Birmingham and Midland Section) (at Birmingham University), at 7.15.—B. D. Porritt: Early Days of the Rubber Industry.

Institution of Automobile Engineers (Wolverhampton Centre) (at Wolverhampton), at 7.30.—H. Briggs: The Elimination of Noise in the Motor Cycle.

Institution of Electrical Engineers (North-Western Centre) (at College of Technology, Manchester), at 7.30.—A. P. Trotter: Illumination and Light (Faraday Lecture).

Institute of Metals (North-East Coast Local Section) (at Armstrong College, Newcastle-on-Tyne), at 7.30.—Prof. F. C. Thompson: The Principles which Govern the Heat Treatment of Non-Ferrous Alloys.

North-East Coast Institution of Engineers and Shipbuilders (Middlesbrough Branch) (at Cleveland Scientific and Technical Institute, Middlesbrough), at 7.30.—S. E. Burgess: Public Works and Housing at Middlesbrough.

Royal Anthropological Institute (Indian Section), at 8.15.—Discussion on Periods in Indian History.

British Institute of Philosophical Studies (at Royal Society of Arts), at 8.15.—A. D. Lindsay: The Theory of Sovereignty and the League of Nations.

WEDNESDAY, January 20.

Royal College of Surgeons of England, at 5.—Sir Arthur Keith: Fossil Remains of Ape and Man (2): The Interpretation of Endocranial Casts taken from Skulls—Ancient and Modern.

Geological Society of London, at 5.30.—T. O. Morris and Prof. W. G. Fearnsides: The Stratigraphy and Structure of the Cambrian Slate Belt of Nantlle (Carnarvonshire).

North-East Coast Institution of Engineers and Shipbuilders (Graduate Section) (at Bolbec Hall, Newcastle-upon-Tyne), at 7.—F. Hamilton: Locomotive Valve Gears.

Institution of Automobile Engineers (Birmingham Graduates' Meeting) (at Birmingham), at 7.30.—E. W. Sisman: The Straight Eight Engine.

Institution of Electrical Engineers (Sheffield Sub-Centre) (at Royal Victoria Hotel, Sheffield), at 7.30.—G. H. Nelson, H. W. Walker, D. M. Rait, and D. H. Davies: Regulations (Short Addresses).

Royal Microscopical Society (Annual Meeting), at 7.45.—A. Chaston Chapman: The Fungi Imperfecti, and a Further Plea for an Institute of Industrial Micro-Biology (Presidential Address).

Royal Meteorological Society (Annual General Meeting), at 7.10.—Presentation of the Symons Medal to Lieut.-Col. E. Gold.—C. J. P. Cave: Address on the Work of the Society during the Past Year, followed by an Exhibition of Lantern Slides of Clouds.

Royal Society of Arts, at 8.—Dr. H. H. Morgan: Problems in Paint and Varnish Technology.

C.B.C. Society for Constructive Birth Control and Racial Progress (at Essex Hall, Essex Street), at 8.—L. Jefferson: Religion and Birth Control (to be followed by a discussion).

Entomological Society of London, at 8.—Annual Meeting.

Institution of Structural Engineers, at 8.—Major R. A. B. Smith: Concrete Roads in America, and the Application of their Principles of Design and Construction to Great Britain.

Society of Chemical Industry (Nottingham Section) (at Nottingham).—Dr. Clibbens: Dyeing and Bleaching of Cotton.

Society of Glass Technology (at Manchester).

THURSDAY, January 21.

Royal Society, at 4.30.—W. Barlow: The Configuration of the Carbon Atom and the Geometrical Relations of this Configuration to those of other Atoms as evidenced in the Chemical and Crystallographic Structures of Organic Chemistry. Part I.—R. E. Gibbs: Structure of a Quartz.—H. J. Gough, D. Hanson, and S. J. Wright: The Behaviour of Single Crystals of Aluminium under Static and Repeated Stresses.—C. H. M. Jenkins: The Determination of the Vapour Tensions of Mercury, Cadmium, and Zinc by a Modified Manometric Method.—*To be read in title only*:—Ursula Andrewes, Dr. Ann C. Davies, and Prof. F. Horton: The Soft X-Ray Absorption Limits of Certain Elements.—Prof. W. L. Bragg and G. B. Brown: The Crystalline Structure of Chrysoberyl.—H. G. Telling: On a Set of Quartic Surfaces in Space of Four Dimensions; and a certain Involutory Transformation.—L. F. Richardson: Atmospheric Diffusion shown on a Distance-Neighbour Graph.—T. Alty: Some Phenomena occurring at the Surface of Bubbles in Water.—A. L. M. Sowerby and S. Barratt: The Line Absorption Spectra of the Alkali Metals.—Prof. A. M. Tyndall and G. C. Grindley: The Mobility of Ions in Air, Parts I. and II.—W. Jevons: A Band Spectrum of Tin Monochloride exhibiting Isotope Effects.—J. H. Andrew, M. S. Fisher, and J. M. Robertson: Some Physical Properties of Steel and their Determination.

Linnean Society of London, at 5.—Prof. Fantham and Dr. Annie Porter: Two Protozoan Parasites in the Latex of *Ficus edulis* and *Euphorbia striata*.—Dr. H. Hamshaw Thomas: The Relations of the Caytoniales with the Modern Flowering Plants.

Royal Society of Medicine (Dermatology Section), at 5.—Prof. Levaditi: Les nouvelles découvertes dans la chimio-thérapie de la syphilis.

Royal Institution of Great Britain, at 5.15.—Prof. C. J. Patten: The Language of Birds.

Institution of Mining and Metallurgy (at Geological Society), at 5.30.

Institution of Electrical Engineers, at 6.—J. L. Thompson and H. Walmsley: Notes on the Testing of Static Transformers.

Royal Aeronautical Society, at 6.30.—Major J. S. Buchanan: The Schneider Cup Race, 1925.

Illuminating Engineering Society (at Royal Society of Arts), at 7.—E. Farmer and others: Discussion on The Lighting of Coal Mines.

Science and Humanism.

IT is sometimes instructive, sometimes amusing, but always interesting "to see ourselves as others see us," even when we think that their view is distorted. To the January issue of the *Nineteenth Century and After*, Mr. G. R. Stirling Taylor contributes an article entitled "The Age of Science," in which he advances criticisms of science and scientific men that are intended to represent the views of the intelligent man in the street. Starting with the assumption that science has dominated the world during the past 100-150 years (he really means the applications of science), he asks whether that domination has been good for man, or whether in harnessing Nature man has not also harnessed himself.

The steam-engine has led to the individual being subordinated to the machine; village life, with its sunshine and fresh air, has been largely replaced by industrial centres, with their slums, their polluted atmosphere, and their noise; and the electric telegraph has caused power to be concentrated in the hands of centralised groups of individuals. In a very real sense the late War was a war conducted by science—by the engineer, the chemist, and the physicist—and for the next war preparations are being made that "may blot out civilisation in a few months at longest." That much good has been done by science, and particularly by medicine, is not denied; but many of the ills that have been cured by it are the result of conditions which science itself has caused. Cold storage has increased our gastronomic temptations and made possible gross profiteering by the holding up of provisions.

Although the man of science may contend that such misapplications of science as chemical warfare are solely the responsibility of those who authorise their practice, the plain man, who cares nought for idealist intentions and is interested only in practical results, will saddle him with the blame: to turn loose a poison gas that may annihilate a city is, in its practical outcome, as immoral as to arm a crowd of drunken savages with knives and revolvers. May not a scientific man with an uncontrolled passion for truth (that is, discovery) be as dangerous as a man who has an unbalanced desire for alcohol?

Mr. Stirling Taylor then institutes a comparison of the man of science with the man of religion. Unlike the former, the priest has never made the amazing blunder of putting material truth in the centre of his altar, and he has never quite forgotten that human welfare is the chief end of life. The laws of both are dogmas, and the plain man will prefer such an unprovable dogma as that there is a God who commands us to do right, to the logically water-tight dogma that a certain chemical procedure will split the atom and blow the world to pieces. "By their fruits ye shall know them," and the real test of the value of science is whether the men who work the machines and live round the factory are the better or the worse for its help and presence. Like the French revolutionists of the Reign of Terror, science has admirable intentions; it is the result which has been so disastrous.

Mr. Stirling Taylor's strictures on the evils accompanying industrial development, due mainly to the applications of science, are not novel; and although they are not entirely without a basis of fact, they certainly lack that very balance which he describes as the secret of life. On the material side he omits a host of directions in which the applications of science have proved beneficial, and he concentrates chiefly on certain unpleasant developments which first became prominent during the War. Throughout his article, he fails to discriminate between the discoverer and the inventor: the man who searches for new things and the man who applies them to human purposes.

In their ethical aspect, human acts can be classified as moral, immoral, or amoral, although the dividing line is not always easy to draw. "A good work of art," said Goethe, "may and will have moral results, but to require of the artist a moral aim is to spoil his work." Whatever view one may take as to the truth of this dictum in the sphere of art, we believe that the first part of it does not apply to science, and that a good piece of scientific work belongs strictly to the amoral category. On the other hand, the latter part of the dictum is certainly applicable: the searcher after truth of all kinds must go forward regardless of consequences, at any rate within the confines of his laboratory or study. The plain man, however, will argue that the social effect of an action cannot be overlooked, even if its morality is determined mainly by the intention behind it; and to this extent we think that Mr. Stirling Taylor is right in stating that a great responsibility falls upon those who discover potential weapons of inhuman warfare; although much greater responsibility must rest with those who use or sanction the use of these weapons. The intelligent man in the street must see that to abandon investigations on lethal weapons while other nations pursue them is to court disaster, if not extinction. However much we may detest these weapons, the calls of home, of country, and of Empire must come first. In these circumstances the responsibility of the scientific workers concerned appears to be confined to the observance of strict secrecy in their work. In almost every other sphere of scientific activity, freedom in publication is essential; but in this case both morality and national security demand that it should be taboo.

The best reply to Mr. Stirling Taylor's article, which deals exclusively with the material applications of science, is supplied by the presidential address, entitled "Science and the New Humanism," which was delivered by the Right Rev. C. W. Barnes, Bishop of Birmingham, to the Science Masters' Association (and will appear in the February issue of the *School Science Review*). In Dr. Barnes' opinion, science has changed the whole background of our thought by giving us a new knowledge of man's origin and place in the universe. Every branch of human thought feels the influence of the new knowledge. The outlook of our grandparents, the postulates of their thinking, have become incredibly remote. Despite certain ills following in the wake of industrial applications, science is ultimately beneficent and not brutal. As an instrument of education, modern science cannot replace what are traditionally called the humane studies; yet knowledge of scientific truth and appreciation of scientific method are indispensable to all, because they are the foundation of modern humanism, and without them human thought would progressively degenerate. Science has practically freed the civilised world from the thraldom of base superstition; it has banished irrational fear; and it has purified religious thought.

The intelligence of civilised man is the outcome of from one to two million years of human and sub-human growth. Not merely do animal instincts and passions survive in us, but the structure of our mind retains traces of an animal past. In times of emotional upset, such as during the War, primitive mental processes assert their vitality; and we go back to the second century of our era to find a parallel to the crazy necromancy, astrology, and magic that flourish to-day. The principle of evolution is now firmly established—as the world's laughter at Tennessee has amply demonstrated. Originally a biological theory, it is now the unifying factor in anthropology, and its influence on psychology is great and growing. Evolutionary psychology and anthropology have given us a more penetrating insight into human civilisation, and in due time they will enable mankind to strengthen his social fabric.

Although science cannot answer ultimate questions concerning matters outside the realm of physical and biological phenomena, it can lead us within that realm from error to truth, from phantasy to fact; and it is on the truth which science has revealed, and is revealing, that we are building the new humanism of our age.

Ideas of God in the Religions of the World.

The Attributes of God: the Gifford Lectures delivered in the University of St. Andrews in the Year 1924–25. By Lewis Richard Farnell. Pp. x+283. (Oxford: Clarendon Press; London: Oxford University Press, 1925.) 12s. 6d. net.

DR. FARNELL'S title is reminiscent of the lofty flights of Scholastic or Puritan divines, but his actual mode of procedure is at once more modest and more modern. It is, in fact, the historical and comparative method which he has already so successfully employed in his "Greece and Babylon" and "The Evolution of Religion." The aim and scope of these lectures, he tells us, is "not so much the problems of the philosophy of religion, but a review of the qualities and activities attributed to God in the religions that are living and have lived," the material for study being the religious literature of the world and to some extent religious art. He therefore proposes to deal "only with the philosophic thought that has borne fruit in real popular belief, not with that which may have only worked in the solitary brain of the eccentric thinker"; and as he several times records his conviction that "a religion without a personal god has not yet been found to be a living and enduring force," the survey is practically limited to beliefs of a theistic type. Buddhism, as a popular religion, he holds to be only an apparent exception to the dictum just quoted, but he does not draw upon it for his materials.

Within the limits indicated, Dr. Farnell offers us in this volume from the wealth of his knowledge a fascinating comparative survey of the main aspects in which men have conceived their deities. For belief in a personal god is by no means to be interpreted as equivalent to pure monotheism, and the chapter on "Polytheism and Monotheism" is one of the most interesting in the book. "The only monotheisms, pure, unmixed, and alive, are Judaism and Islamism," while in the past we have the creed of Ikhnaton, the reforming king of Egypt, and possibly the teaching of Zarathustra in its original form. As regards Christianity, Dr. Farnell says "the current popular religion of Europe should be rather described as a high spiritual polytheism tempered and restrained by the Athanasian Creed," while the cult of the Virgin and the saints reminds us that "Mediterranean polytheism was never permanently overthrown, and that many of its fibres survive in the soil of our orthodox Christianity." Similarly he notes that among the higher world-religions the only two that have remained consistently non-idolatrous are the Judaic and the Islamic. The early Christian church "upheld for a time the Judaic ideal, but the spirit of the Hellenic and Mediterranean idol-lover triumphed soon over the spirit of Moses; the resistance of the Byzantine iconoclastic emperors was futile; and the popular religion of Christendom, except within the shrinking borders of Puritan Protestantism, must to-day be called idolatrous." But, as might be expected from the author of "Cults of the Greek States," Dr. Farnell does full justice to the nobler side of "Hellenic idolatry" and its important contributions to religion as well as to art. He emphasises in another connexion the fact that, while wisdom in other religions is exalted as a divine attribute and God's highest gift to men, this is always understood in a moral-religious sense; only in Greek religion do we find the consecration of knowledge as such, the recognition of the life of the thinker and the man of science as divinely inspired and a reflection of the divine activity.

Nature-worship and tribal religion are dealt with in separate chapters, and the progress traced from tribal particularism to the conception of a universal God. A long chapter is devoted to "the moral attributes of God" and another to the attribute of power, while the concluding chapter, on "the metaphysical attributes," leads inevitably to some discussion of the problems of the philosophy of religion, which the author began by setting aside. Power is the earliest attribute of the divine: "the gods or the spirits are imagined as powerful before they are recognised as beneficent or just." With the development of monotheism the divine power is characterised as omnipotence, conceived at an early stage as the omnipotence of an arbitrary despot, but eventually as manifested in the law and order of the universe. The question of miracles and of the real validity and religious value of prayer is shortly discussed in this connexion, and Dr. Farnell recognises here, as elsewhere, "the wide cleavage that at present exists between the highest theistic thought and the popular religion."

In the concluding chapter Dr. Farnell dismisses as valueless for religion the philosophical conception of the absolute, if understood as "the All-in-All of the Universe." "Worship, the accompaniment of all active religion, and Love, the essence of the highest, seem both impossible and irrelevant to the impersonal All-in-All, besides which there is no other." He criticises the metaphysical attributes of eternity and immutability, commonly accepted in philosophical and religious thought as characteristic of the divine. Timelessness, he holds, is inconsistent with creation, and the changeful is not necessarily the imperfect. "If we could imagine an unending series of changes from one perfect state to another, we should not view it with regret; each succeeding state of being or phase of creation might be new but none the less perfect, and the sense of change might become an added joy." The final riddle, how to reconcile the existence of the evil and pain in the world with the ideal of an omnipotent and beneficent God, Dr. Farnell pronounces to be insoluble. After quoting a sentence of Lotze to that effect, he adds: "'Though he slay me, yet will I trust in him' is the highest religious expression for this self-abnegation of the intellect. And this may well be the last word of wisdom." But although such a conclusion may be forced upon us, such self-abnegation is far from being, in his view, a thing to be gloried in; as he puts it on his last page, "a religion that makes intellectual assumptions incurs intellectual obligations, and cannot admit the claim, occasionally made in our pulpits, that incoherence and self-contradiction are proofs of the highest truth."

Steam Condensing Plants.

(1) *Modern Practice in Steam Condensing Plants: a Practical Treatise.* By Arthur R. Wright. Pp. xv+309+vi. (London: Crosby Lockwood and Son, 1925.) 45*s.* net.

(2) *Steam Condensing Plant in Theory and Practice.* By James Sim. Pp. xiii+271. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1925.) 18*s.* 6*d.* net.

HITHERTO the subject of steam condensing plants has not received the attention to which its importance in the achievement of efficient power production entitles it. Difficulties have confronted the student of the subject. In the first place, research has yet much to accomplish in this direction, and further, such information as was available was not in the most accessible form, being principally confined to papers and articles which have appeared sporadically.

Now, almost simultaneously, two books appear, both making a commendable attempt to deal comprehensively with the whole field, and collect the available facts into a form which will be useful to those seeking information on the subject. Both have succeeded extremely well on different lines. One is principally useful for its descriptiveness and its collection of information and references, and the other for its analytical and mathematical treatment of the physics of the subject. Neither touches upon the considerable development which has recently been made in condensers for turbine-driven locomotives, but, presumably, it has been considered that that development, being almost exclusively Continental in origin, is not as yet of interest to the British engineer. Apart from that fact, comprehensiveness is a marked feature in each volume, and, unlike the majority of technical books, they fill a real gap in the library of technical literature.

(1) Mr. A. R. Wright commences his work at the root of the subject by stating in the opening chapter fundamental laws and the properties of steam, but it is unfortunate that the arithmetical errors in the examples given will tend to confuse the novitiate who finds this chapter necessary, and at the same time will create a bad first impression.

The various factors affecting the transmission of heat through condenser tubes are separately discussed and the work of accredited experimenters is effectively summarised. Analysis of their findings is not attempted, but the diagram showing collectively the results of the best known experimenters regarding the effect of cooling water velocity on the rate of heat transmission through tubes is useful. The merits of the various types of jet condenser, high and low level, counter and parallel flow and their adaptability to conditions, are well set out. Ejector, injector, exhaust steam induction and evaporative condensers are similarly dealt with and discussed, in all cases with good diagrams and illustrations. The principles of the operation of cooling ponds and towers are explained, and it is shown that the former will rarely be preferred to the latter. This is an excellent chapter and an exceedingly welcome contribution.

The functions and requirements of the surface condenser and the application of the laws of heat transmission thereto are next dealt with. A good selection of types are illustrated, but in their description, otherwise good, more attention might have been directed to the effect of baffles in maintaining the condensate temperature and to the features aiming at reducing resistance to steam flow across the tubes. Tube corrosion and its prevention are only briefly referred to, but, of course, this is a major problem in itself. The treatment of those important auxiliaries—the air and condensate extraction pumps—is appropriately thorough. Air pumps of every type, reciprocating, steam jet, water jet, rotating jet, and combinations of these, with and without intercoolers and after-coolers, are capably described. The circulating pump, not being exclusively a condenser auxiliary, receives less attention, but its functions and requirements are explained. Brief reference is made to de-aerators, oil separators, vacuum breakers, relief valves, etc. The note on commercial considerations in the choice of plant might have proved a valuable contribution, but the costs given are pre-War, and consequently have not much present-day value, even relatively to each other.

The mathematical treatment is perhaps purposely of an elementary nature, but it requires some revision, and the diagrams in the appendix also require a little attention, while a future edition could with advantage include statements of the performances of actual installations, properly correlated and compared. The book is very well illustrated and is a splendid compendium of the various forms and functions of apparatus relating to the condensation of steam, while the copious references to further sources of information are of great value.

(2) Although the preface states that Mr. Sim's book is written for students, it will have a much wider field than that implies, for on this subject many engineers are much in need of sound information such as is contained in this volume. The book may be summarised as a thoroughly sound application of known physical facts to the design of steam condensing plant. It deals with surface, jet, ejector, and evaporative condensers, air pumps and air ejectors, centrifugal pumps for condensate extraction and for supplying cooling water, evaporators and feed water heaters, in regard to each of which a sound method of design and much valuable data are given, while feed water systems and de-aerators and details appertaining thereto are fully discussed. In all cases some useful examples of the products of well-known manufacturers are illustrated and described. Surface condensers are properly considered the most important, and in dealing with the factors affecting the rate of transmission of heat through the walls of the tubes, the method has wisely been adopted of regarding the resistance to heat flow as being composed of individual resistances which can be separately treated. Data for determining the values of these various resistances are given, and since these data are said to agree with the author's practical experience, which must be exceptionally wide, they should be of great utility. It is true that the figures given for the greatest resistance, that on the steam side of the tube, have a wide variation (in one case the maximum value is twice the minimum), but, in order to cover the great variety of practical conditions, this is unavoidable in a general treatment of this kind.

The selection of a proportion of the known total resistance to be allocated to each separate cause is probably of a somewhat arbitrary nature, unavoidable in the present state of knowledge, but it would appear that the arbitrariness is carried a little further than is necessary. For example, it is not clear why the resistance at the surface of separation of the tube wall and the cooling water should be different in a brass condenser tube and a copper feed heater tube of the same bore, or why this resistance should be different with a thin copper tube and a thick copper tube; again, in regard to the resistance across the tube wall itself, a brass condenser tube 0·048 in. thick has a value of 0·08 ascribed to it, while a copper feed water heater tube 0·064 in. thick has, in the same units, a value of 0·3—several times that estimated with regard to the respective conductivities and dimensions. If there are reasons for these apparent discrepancies, the student would prefer to know them. These comments are made rather in response to the prefatorial request for suggestions than in criticism or lack of appreciation of the general value of the work.

Useful data are given for determining the head necessary to overcome the resistance to flow of cooling water through condenser tubes, pipes, etc. The design of air coolers, their influence on the capacity of the associated air pumps, etc., and the conditions under which their adoption is justified, are lucidly explained. A useful coefficient of condenser performance is suggested involving the terminal temperatures of the steam and cooling water. Air pumps and air ejectors receive the attention their importance demands, and again good methods and useful data are given for determining their proportions to suit the service required.

The mathematical treatment is sound throughout and presented in such a form as to be readily assimilated, while numerous examples are worked out to show practical applications. Instructive examples are also given to indicate how data can be analysed to detect the functioning of an existing apparatus, but that in which the dryness of the engine exhaust is deduced from the condenser temperatures should have been accompanied by a note of warning. The corrosion of condenser tubes is a matter not touched upon, and although it is too wide a subject for full treatment in a general work of this kind, some reference to it, however brief, would be an improvement.

The general value of this publication may be gathered from the fact that in it there is the necessary matter to enable any one skilled in the art to undertake the rational design of condensers and their auxiliaries to meet the ordinary requirements of practice.

L. M. D.

The German Outwash Terraces and the Astronomical Theory of the Ice Age.

Die Gliederung und absolute Zeitrechnung des Eiszeitalters. Von Prof. Dr. W. Soergel. (Fortschritte der Geologie und Paläontologie, Heft 13.) Pp. vi+125-251+3 Tafeln. (Berlin: Gebrüder Borntraeger, 1925.) 8·25 gold marks.

THE revision of the astronomical theory of the Ice Age, usually associated with the names of Adhémar and Croll, and its recasting in a form which seems to show considerable correspondence with the observed facts of geology,[1] has led Prof. Soergel to attempt an interpretation, in terms of this theory, of the complex terrace system of certain German rivers.

---

[1] W. Koppen und A. Wegener, "Die Klimate der geologischen Vorzeit." Berlin, 1924.

The Köppen-Wegener curves for the secular variation in summer sunshine for latitudes 55°-65° show four well-marked double minima, corresponding to the four ice ages of the Alps, Günz, Mindel, Riss and Würm, and three intervening periods of variable but on the whole warmer conditions, supposed to be identical with the interglacial periods. The double character of the minima and the excessive length of the middle interglacial period give some grounds for confidence, for it will be remembered that Penck established on geological evidence a double maximum for the Würm Ice Age and proved that the Mindel-Riss Interglacial Period was several times as long as those which preceded and followed it.

Now the valleys stretching away from the Alps exhibit a fourfold terrace system, one terrace for each glaciation, but when we come to the river valleys containing the outwash terraces of the northern glaciation, we find a much more complex state of affairs. Here there are, according to Prof. Soergel's reading, ten terraces, nine of which yield a cold fauna and one a temperate fauna. Eight of these terraces are accommodated by the four double minima corresponding to the Alpine Ice Ages. The curve of summer sun-heat shows, however, in addition to these, many other minima, four of which, though considerably less than those of the Ice Ages, are greater than the others (Fig. 1). They occupy positions as follows: (*a*) Pre-Günz, (*b*) Pre-Riss, (*c*) Pre-Wurm, (*d*) Post-Würm (or Würm 3). The Pre-Günz minimum is supposed to be inoperative, the pole being at that time too distant. To the Pre-Riss and Pre-Würm are ascribed the two "supernumerary" terraces, that with the temperate fauna falling on the Pre-Riss. To the Post-Würm minimum are attributed the Bühl stadium of the Alps and the Baltic re-advance of the northern glaciation. There is no terrace in the German river valleys corresponding to this last minimum. An explanation of this failure is promised on p. 199 [75], but the reviewer has been unable to find it in the subsequent text.

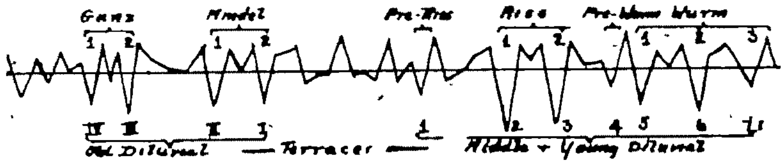

FIG. 1.—Comparison of the terraces of the Ilm with the astronomically calculated curve of summer sun-heat.

A further test of the equivalence of the astronomical and geological records is applied by estimating the erosion which took place between the formation of the terraces, and comparing this with the lengths of the astronomically calculated interglacial periods. No direct relation is observable, and various factors are mentioned as likely to cause abnormalities in this respect. Of these, the most satisfactory is the occurrence of excessive maxima of sun-heat in certain periods in which the erosion is greater than the duration of the period might seem to justify. Crustal movements, changes of sea-level, and hardness of rock are also considered to have an effect, which is, however, less easy to assess.

It is difficult at the present moment to form any well-founded opinion on the merits of an attempt of this sort. One reads it with the fear that it is perhaps merely a renewal of the reckless "pigeon-holing" or fitting of facts into an artificially prepared scheme, which was carried to such extremes by James Geikie and his followers. On the other hand, the scheme on this occasion seems to be based on a securer foundation, and there is a fair amount of fitting between the facts and the theory. It is questionable, however, if this appearance of agreement is beyond the possibilities of coincidence, and the confidence of the reader is far from being reinforced by constantly recurring assertions regarding the conclusiveness of the argument.

The essential portion of the book is followed by a discussion of the importance for geology, palæontology, and archæology of an absolute time scale of this kind. Probable dates in years are assigned to the Palæolithic stages, the chronology of Penck being followed approximately, and the Chelléen being regarded as belonging to the Mindel Riss instead of to the Riss-Würm, where it is placed by Obermaier and the Abbé Breuil. This section is interesting, but the treatise as a whole seems quite unnecessarily prolix, and might with advantage be condensed into half the space.

W. B. WRIGHT.

Fœtal Monkeys.

Angola et Rhodesia (1912–14). *Mission Rohan-Chabot sous les auspices du Ministère de l'Instruction publique et de la Société de Géographie.* Tome 4: *Histoire naturelle.* Fascicule 1: Mammifères (Anatomie comparée, embryologie); oiseaux, reptiles, poissons. Pp. viii + 176 + 18 planches. (Paris: Paul Geuthner, 1923.) n.p.

THIS fascicule contains a systematic account of the birds, reptiles, and fishes collected in Angola and Rhodesia by M. de Rohan-Chabot in 1912–14. But the major portion of the volume is devoted to a report upon the anatomy of two fœtal baboons. The special value and significance of this investigation are due to the fact that it was carried out at the Laboratory of Comparative Anatomy of the Natural History Museum in Paris by such competent and experienced anatomists as Profs. R. Anthony and F. Villemin.

The memoir represents a good deal more than the mere description of the two fœtuses of the Chacma baboon, and the bones of their respective mothers. The authors have collected all that is known of the anatomy of the viscera and skeleton in fœtal monkeys and apes, so that their report forms a very useful and important addition to our knowledge of the comparative anatomy and embryology of the Primates. Moreover, they have directed attention to several very suggestive and novel problems involving the correlation of function with morphology. It is not possible within the compass of this notice to summarise all the provocative hypotheses they put forward in a tentative way. Hence I must content myself with a reference to one of them.

While the fœtal kidney in man is lobulated, those of the tailed monkeys and lemurs are smooth, and the condition found in the anthropoid apes is intermediate between the catarrhine and the human. Discussing this curious phenomenon, the authors invoke the influences of climatic conditions and size of body as factors that play a part in causing lobulation. In 1922 Prof. Anthony discussed the reasons for the persistence into the adult stage of obvious lobulation of the kidney in such mammals as whales, elephants, bears, etc.; and he put forward the suggestion that the reduction of the relative extent of the skin (and of the ability to get rid of waste products by sweating) in proportion to the bulk of the body in large creatures was compensated by the increased activity of a kidney broken up into a large number of lobes. The fact that certain small mammals also have lobulated kidneys he explained by the fact that they live in cold climates, which reduces the sudorific activities of their skin.

In this memoir the authors attempt to apply these hypotheses to explain the conditions found in the Primates. In man and the giant anthropoids the great size of the body is a reason for lobulation of the kidney, which is less pronounced in the apes because they ive exclusively in tropical climates. The authors state hat in fœtal negroes from Africa the lobulation is less pronounced than it is in Europeans, and claim that this esemblance to the anthropoids is due to the fact that, ke the latter, the kidneys of these tropical Africans have been influenced by the climatic conditions under which they live.

Such far-reaching conclusions obviously call for a wider basis of evidence than is yet available before hey can be accepted as the true interpretation of the acts.

G. ELLIOT SMITH.

Our Bookshelf.

Structure des molécules. Par Prof. Victor Henri. 1: Polarité des molécules; 2: Structure des molécules déterminée par les rayons X; 3: Spectres d'absorption des vapeurs et structure des molécules; 4: Prédissociation des molécules; 5: Structure du benzène et de ses dérivés. Conférences faites au laboratoire de Ch. Moureu et à la Société de Chimie physique. (Publications de la Société de Chimie physique, 12.) Pp. ii+122+1 planche. (Paris: J. Hermann, 1925.) 20 francs.

Now that our knowledge of the structure of the atom is beginning to be very definite, it is natural to turn to the molecule. Here a much more complex problem presents itself, but, of recent years, several promising lines of investigation have been developed. As is to be expected, stress is laid on the interpretation of absorption spectra, a subject which Prof. Henri has made peculiarly his own. These spectra are exceedingly complicated, but it is now possible in many cases to identify the separate effects of the rotation of the molecule, the vibrations of the component atoms and the movements of the electrons. From these measurements it is possible to calculate the energy of the molecule in its various states of activation. Emphasis is laid on one important general result among others: that while in the normal state and the early states of activation the rotation movements of the molecule are subject to quantum restrictions, at a certain stage of activation this quantisation ceases. To this state Prof. Henri gives the name "predissociation" and claims that it is the necessary prelude to chemical action and combination.

In a short chapter devoted to X-rays and molecular structure the author is clearly on less familiar ground. Here a few errors have crept in, notably in his discussion of the symmetry of the benzene ring, where he misquotes Bragg as suggesting a model with symmetry properties which are actually mathematically impossible. The first chapter gives a lucid account of the electrical moments of molecules, while the final chapter is devoted to the vexed question of the structure of the benzene ring. A new suggestion is made which the author claims is in better agreement with the facts that are at present known than any of the older models. The book contains a very useful summary of the recent methods of attack on the question of molecular structure, and the reader can scarcely fail to be interested in and impressed by the progress made on a problem which only a few years ago appeared almost impossibly complicated.

Public Health in Theory and Practice: an Historical Review. By Dr. William Henry Welch. Pp. viii+51. (New Haven: Yale University Press; London: Oxford University Press, 1925.) 4*s.* 6*d.* net.

THIS little book, which is the eighth work published by the Yale University Press on the Williams Memorial Publication Fund, is the second annual lecture in commemoration of William Thompson Sedgwick, the pioneer in American hygiene, a memorial volume to whom we noticed in our issue of March 14, 1925, p. 372. Dr. William Welch, who is Director of the School of Hygiene and Public Health at Johns Hopkins University, Baltimore, shows that the justice of Sedgwick's claim that "the sanitarian needs a proper working theory" has been well illustrated in the history of preventive medicine, especially in the work of Fracastorius, Sydenham, Jenner, Sir George Baker, James Lind, Sir John Simon, and Pasteur. It is pointed out that inadequate and even erroneous theories which bear some relation to the state of contemporary knowledge may serve a useful purpose, as was exemplified by the doctrine of the so-called "filth theory" of the generation of epidemic diseases, especially typhus, typhoid, and dysentery, inasmuch as the acceptance of this theory led to a campaign for the supply of pure water, the proper disposal of sewage, the prevention of water pollution, the removal of nuisances, cleanliness of the streets, inspection of food, healthfulness of dwellings, ventilation, and proper disposal of the dead.

In conclusion, Dr. Welch deplores the lack of active participation on the part of the general medical profession in public health activities, the fault being partly due to encroachment on the field of the private practitioner and partly to a lack of sympathy and co-operation with health officials and with health programmes on the part of the practitioner.

General Zoology. By Prof. H. L. Wieman. (McGraw-Hill Publications in the Zoölogical Sciences.) Pp. ix+312. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1925.) 15*s*. net.

THIS book "is a rather condensed account of some of the outstanding facts and principles of zoology" prepared for use in conjunction with the author's course of practical teaching, and it is evident that a clear understanding of many of the subjects must depend largely on the work on structure and on histology done in the laboratory. The first eighteen chapters of the book deal with adaptation, the various systems of organs, metabolism, cell division, gametogenesis, ontogenesis, evolution and heredity, and a concluding chapter gives a "general survey of the animal kingdom" in fifty pages. The best chapters, in our opinion, are those on evolution and heredity; many of the other subjects are treated so briefly as to be largely ineffective, *e.g.* reproduction—agamic, hermaphroditic and bisexual—intrauterine development and certain general considerations are traversed in eight pages, more than two of which are occupied by illustrations. The author should have eliminated a number of loose statements, *e.g.* that the ilium of the frog "extends dorsally to the scapula," that the setæ of earthworms are arranged in clusters, and should revise his usage of the term nephridium. The illustrations are carefully chosen and well reproduced.

Manufacture, Design, and Laboratory Work. Compiled and collated by D. V. Onslow. (Electrical Engineers' Data Books, Vol. 2.) Pp. xvi+276+cxcv+9. (London: Ernest Benn, Ltd.; Radio Press, Ltd., 1925.) 15*s*. net.

ENGINEERING data of the manufacture and design of electrical machinery and also descriptions of tests which are useful in laboratories and testing rooms are given in this work. The book opens by discussing the electric strength of insulating materials, and we gather that electric strength has something to do with "average breakdown voltage." The impression left on the reader, however, is that possibly there is no such thing as "electric strength" after all. The scientific man will be appalled at the many trade names of insulating materials. The methods of testing devised by members of the various research committees have strictly practical ends in view, and a large "tolerance" has to be allowed for the results. We have a difficulty in understanding what is meant by saying that the power factor for clear micas is 0·003. The phrase "dielectric constant" is rather an unfortunate one, when we have to discuss how it varies with temperature, humidity, etc. In the appendix it is called specific inductive capacity. The type in which the mathematical tables is printed is difficult to read. In our opinion it is time that the so-called "international and B.O.T. units" were placed on the scrap-heap. The ampere, the volt, and the ohm have been determined with an accuracy far in excess of that required in commerce.

Abhandlungen zur Physiologie der Sinne aus dem physiologischen Institut zu Freiburg i. B. Herausgegeben von J. von Kries. Fünftes Heft. Pp. iv+120. (Leipzig: Johann Ambrosius Barth, 1925.) 4 gold marks.

IT is much to be regretted that in Great Britain there is a decay of interest in the physiology of the special senses. Among representative physiologists, there are extremely few who might be called special sense physiologists. The present volume bears witness, however, that this is not the case in Germany. The volume is a convenient fasciculus, the fifth of its kind, forming in reality a reprint of collected papers published from the school of von Kries in the *Zeitschrift für Sinnesphysiologie*. The papers describe congenital colour-blindness in one eye (J. von Kries), similarity of taste in mixed solutions (E. v. Skramlik), minimal luminosity in colour sense (E. Engelking and F. Poos), and the geometric representation of multiplicity of sensations (J. von Kries). Each contribution must be studied first-hand for its merits.

L'Hydrogène et les gaz nobles. Par Dr. J. J. Van Laar. Pp. ii+79. (Leyde: A. W. Sijthoff, n.d.) n.p.

THIS monograph is the first of a series on theoretical and practical chemistry to be issued in French or English under the auspices of the Société Chimique Néerlandaise. Devoted exclusively to consideration of numerical data relating to the physical properties of the gases specified in the title, it will be welcomed by all workers in this branch as a trustworthy, well-arranged, and reasonably up-to-date book of reference

Exercises in Geometry. By V. Le Neve Foster. Part 1. Pp. viii+69. (London: G. Bell and Sons Ltd., 1925.) 2*s*.

MR. FOSTER thinks it is not inconvenient to add to the number of riders given in the text-books. If he is right, it would be difficult to provide a better collection than this, which is intended to be used in Stage I. when the stress is laid upon the practical sid of geometry.

Hardness.

AMONGST the many properties of solids which are the subject of measurement, none are less satisfactorily specified than that of hardness. Two kinds of hardness may be distinguished, namely, surface hardness and body-hardness, though the distinction is often disregarded. Mineralogists deal with surface hardness, and of any two bodies call that the hardest which will scratch, but not be scratched by the other. On this system an arbitrary scale has been evolved having diamond (Hardness 10) at one end and talc (Hardness 1) at the other.

Engineers are chiefly concerned with body-hardness, which (in the most usual test) is measured by the depth or diameter of the impression left on the surface of the material tested, when a hard steel ball is pressed against it by a known force. Other forms of test are also in use, but in all cases the hardness is given by a number and not in mechanical units. Body-hardness, however, may be simply defined as the greatest normal pressure which a surface will bear without rupture. More than twenty years ago I tried to get the Ordnance Committee to have its hardness tests stated in this way, but nothing came of it.

In scratching tests the conditions are more complex. The harder of the two bodies exerts a tangential drag on the surface of the softer, and a scratch is produced when this drag exceeds the limit of distortion at a free surface. The coefficient of friction between the pair is, therefore, involved; and it is probable also that the distortion limit at the surface may differ from the corresponding limit for the interior from causes analogous to those which produce surface tension in a fluid. Even for body-hardness the same cause may operate to a small extent.

It may happen, therefore, that the scratching and indentation tests indicate different degrees of hardness in the same material.

As regards indentation tests, it must be noted that they are of use only when the indenting body is much harder than the indented, and also when the limits of elastic deformation of the latter are small. The ball test, for example, applied to a sheet of india-rubber would indicate infinite hardness, since no permanent impression could be made.

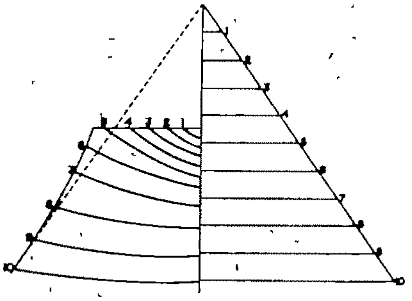

FIG. 1.—Showing the deformation which occurs when the apex of a cone is flattened. The curves are copied from an axial section of a cone built up of coloured strata of plastic material.

In the course of some experiments made during the year 1925 on the properties of various steels, I have had occasion to make many measures of their hardness, and for this purpose have employed a method which is free from some of the above objections.

A small piece of the material to be tested is shaped into a circular cone which is placed point downwards in a loaded vertical holder, provided with a means of slowly lowering the point until it rests on, and is entirely supported by, a hard flat surface. The pressure flattens the point of the cone until the area of contact is sufficient to carry the load, and the diameter of the flat is then measured with a microscope and micrometer.

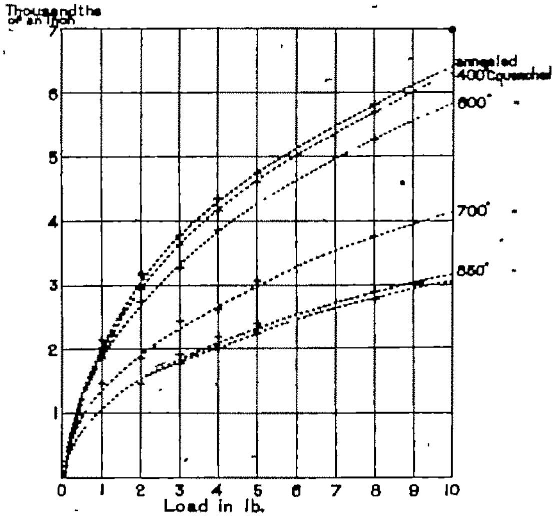

FIG. 2.—The ordinates are the diameter of the flats formed by pressure on the apex of cones of carbon-steel (Stubbs's steel rod) when hardened by quenching at different temperatures. The abscissæ are the applied loads

In these experiments the hard surface was a piece of polished sapphire. Diamond no doubt would be preferable, but a suitable stone would have cost as many pounds as the sapphire did pence, and sapphire is so much harder than any of the metals that in this case the results would be identical.

The nature of the deformation set up in the flattened cone is shown in Fig. 1.

If the coefficient of friction between the surfaces over the area in contact is known, the deformation curves can be calculated, and it can be shown that the pressure is nearly uniform over the whole surface, but in the figure they are copied from an experimental model. Sheets of a plastic substance of uniform thickness and quality, but differently coloured, were placed on one another, and from the stratified block thus formed, a cone was cut by means of a properly guided and tightly stretched fine steel wire. The cone was then pressed against a flat plate by a motion parallel to the axis, and an axial section cut showing the distortion of the strata.

For any given angle of cone the curves are similar, whether the flattening is large or small; and supposing that the material is isotropic, that is, neglecting any peculiarity belonging strictly to the surface layer, hardness may be estimated by the pressure between the two plane surfaces involved.

If D is the diameter of the flat, this pressure is Load $\times 4/\pi D^2$, and for any particular material D should be proportional to the square root of the load. The experimental results illustrated in Fig. 2 (and in the many similar diagrams which have been plotted) show that this is actually the case. In this figure the ordinates of the dotted curves are proportional to the square root of the abscissæ which represent the loads, while the crosses are the measured diameter of the plate. If the diameter of the flat is n thousandths of an inch and the load on the cone is m pounds, the pressure on the flat is $565m/n^2$ tons per square inch (nearly).

A series of curves for various values of m (see Fig. 3) (in which the ordinates refer to n and the abscissæ pressure) may be drawn so that the hardness for any values of n and m may be found by inspection. Fig. 2 relates to Stubbs's steel rod hardened by quenching in water from different temperatures. When softened by slow cooling the hardness is less than 100 tons per square inch.

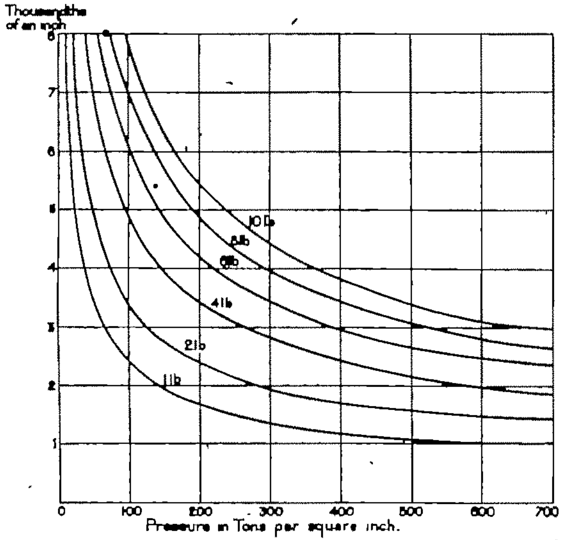

FIG. 3—Diagram to enable the hardness of a material to be determined by inspection for any load and diameter of flat. The ordinates are the diameter in thousandths of an inch, and the abscissæ the hardness in tons per square inch.

The maximum hardness is attained when the quenching temperature is rather lower than 900° C. and is then well above 600 tons per square inch. It was a surprise to me that any metal could withstand such a pressure without crushing.

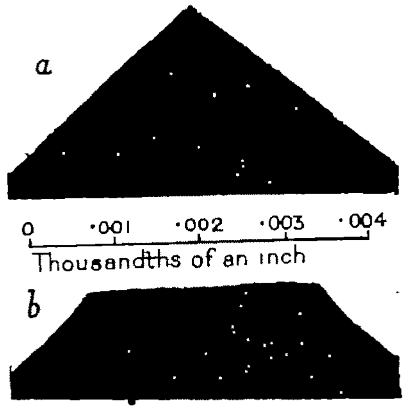

FIG. 4.—Photographs of a hard steel cone (a) Untouched, (b) after the application of a pressure of 610 tons per square inch.

In Fig. 4 two photographs are given of the same steel cone before and after this pressure was applied. A few measures of the effect of tempering have been made, and these are included in the subjoined table, but they will be repeated in greater detail.

In the case of alloy steels the effects of quenching are very complex, sometimes increasing and sometimes diminishing the hardness, and the differences in their behaviour seem to have no simple relation to the proportions of the alloying metals (manganese, chromium, and nickel), but none of them under any conditions which I have tried approaches the hardness of carbon steel.

For the softest of my specimens (36 per cent. nickel) the hardness was about 70 tons, and for the hardest (13·5 per cent. chromium) 300 tons.

HARDNESS OF VARIOUS MATERIALS.

The hardness is stated as the maximum pressure which the surface of the material will withstand.

Soft Iron.	Hardness Tons per sq inch	Remarks.
1	68	Nearly pure iron about 0·04 per cent carbon
Carbon steel		Stubbs's steel rod
1	150	" " as sold.
2	155	Annealed by slow cooling from dull red heat.
3	158	Quenched at 400° C.
4	164	" 600°.
5	265	" 700°.
6	540	" 850°
7	610	" 900°
8	500	" 800°, tempered at 100°.
9	350	" " Straw yellow.
10	290	" " Blue

Alloy Steels	As from the Rolls	After Quenching at 900°.	Composition of Alloys per cent.				
			C.	Si.	Mn.	Cu.	Ni.
1	190	165	0·15		5·4		
2	197	220	0·15		15·3		
3	250	330	0·35	0·22	0·13	13·6	
4	112	265	0·43	0·32	0·25	3·3	
5	114	210	0·19	0·20	0·65		4·0
6	94	75	0·16	0·03	0·86		36·0
7	145	135	0·6		5·0		15·0
8	93	Sample of Invar	Analysis not known.				

Miscellaneous.		
Brass	70	Hard drawn commercial rod.
Copper	39	16 B W.G. wire.
Aluminium	24	Commercial drawn rod
Tin	7·25	Commercial
Lead	5·3	Commercial
Beeswax	0·14	At 14° C The hardness varies rapidly with the temperature.

As bearing on the accuracy of the measures here given, it will be seen on reference to photograph *b*, of Fig. 4, that the angle between the flat and conical surface forms very definite positions on which to adjust the micrometer wire. With the magnification employed, each division of the micrometer was equivalent to rather less than one sixteen-thousandth of an inch. Repeated readings of the length of the same diameter seldom varied by more than one micrometer division. For the hardest metals this diameter was of the order of 0·003 in., so that the linear error would not exceed 2 per cent. and the error of area 4 per cent.

It was found, as might have been expected, that near the apex of the cone the cross section was generally somewhat oval, and for this reason two diameters at right angles to one another were always measured and their mean used in computing the area.

Taking all sources of error into account, I believe the results to be generally correct within 5 per cent.

Phenological Observations and Results in Russia.

PHENOLOGICAL studies are not a new branch of scientific research in Russia; they have, indeed, a long history.

After the first efforts to make and to publish phenological observations, the attempts of N. Annenkoff in Moscow (1844–49), of A. Doëngingk in Kishinev (1845–60), and of Prof. A. Voeikoff (1885–95), phenological observations were established on a real scientific basis and were carried on during the long period from 1888 to 1923 by the Russian pioneer of this branch, the late professor of the Institute of Forestry, D. N. Kaigorodoff. He not only made very careful personal phenological observations every spring and autumn in the Lesnoi Park, near Petrograd, but organised them also over all Russia by many correspondents, whom he had recruited.

After Prof. Kaigorodoff's death in 1923, at the age of seventy-seven years, his work was taken in hand by the Russian Society of Amateurs of the Study of the Universe ("Obstchestvo Mirovedenja"), an entirely private society of amateur astronomers and meteorologists.

This Society elected a special Phenological Committee, which undertook the organisation of a large network of phenological observation points and also the compilation, study, and publication of the results. Through appeals to its correspondents and through propaganda in newspapers, the committee has greatly developed this during the last two years. In the year 1924 there were 258 observers, corresponding with the committee, in 223 different stations in the U.S.S.R., and in the spring of 1925 the number of observers increased to 608 at 512 points. At nearly 75 points in European Russia phenological observations had been made for periods of 10-20 or more years.

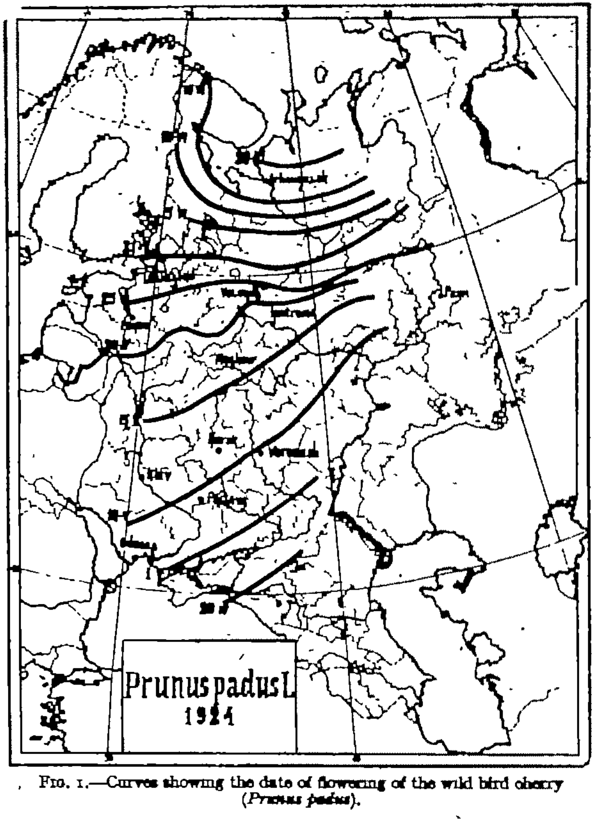

FIG. 1.—Curves showing the date of flowering of the wild bird cherry (*Prunus padus*).

Besides these points of observation of the committee there is a network of 58 points organised by the Meteorological Bureau of the Ukraine (South Russia).

The study of the large series of observations made at different points and during a long series of years permitted the Phenological Committee to draw up a table of the mean times of different natural phenomena at 17 typical centres distributed over all European U.S.S.R.

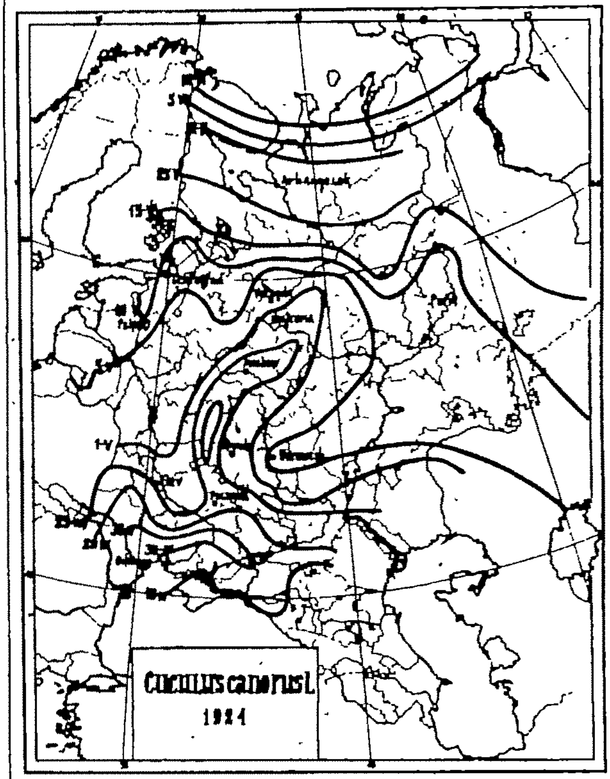

FIG. 2.—Curves showing dates when the cuckoo was first heard.

This table affords the possibility of comparing the natural phenomena of every spring and autumn with the mean times, and of deciding how far either event is too early or too late in the present year.

Such observations compared with results of the meteorological observations show generally a coincidence with weather conditions. A more precise idea of the gradual procession of the natural phenomena and of their dependence on meteorology can, however, be obtained also in another manner. Having a dense network of observation points, we can easily draw curves of isochronous events—*isopiptesses* in the case of the arrival of birds, and *isoanthes* for the flowering of plants.

The Phenological Committee has tried to draw some curves for the spring of 1924, and also for the spring of 1925, and has obtained very interesting results.

The isoanthes in 1924 of the earlier plants (Fig. 1), as, for example, of the flowering of the wild bird cherry (*Prunus padus*)—a tree very common and widely distributed in Russia—in the south and middle part of U.S.S.R. lie in a N.E.-S.W. direction, showing that in the east part the flowering began earlier than in the west part of the country, where it was retarded by some unfavourable conditions. But in the north part they lie quite regularly in a later period, 25, v.-20, vi. (Roman numerals refer to months of the year) The flowering of the lilac (*Syringa vulgaris*) shows nearly the same conditions.

The first cry of the cuckoo (Fig. 2) gives greater complications: the curves make a large tongue-like projection to the north, showing that the arrival of this bird was retarded in the east as in the west, but that it succeeded in progressing on the nearly meridional line Poltava — Moscow — Kostroma — Vologda in the central part of U.S.S.R.

The explanation of this strange direction of curves is given by the study of the isobars of this spring. The isobars of 20, iv. are nearly parallel to the latitudes, as also are the isopipteses of the cuckoo at this time. But on 23, iv a very strong cyclone burst in from the north-west and occupied the whole space between the Baltic and the Black Sea. The temperature fell and snowfall was recorded everywhere in this region so far as Kursk and Voronesh. The distribution of winds in this cyclone was such that in the middle part of Russia they were directed from south to north, and this is observed quite on the line Poltava—Moscow—Kostroma. West and east of this line the winds blew in the opposite direction. By these winds the cuckoo was driven northwards on the given line and retarded west and east of it.

On 5, v. the isobars changed in such a way that in the north-east of Russia a strong anticyclone formed in the region of Volga and Kama. Therefore we see on the isopipteses of 10, v. and 15, v. that the cuckoo was rapidly progressing in this direction and heard, 10, v., north of Perm. New cyclones formed in the north-west part brought the cuckoo also to Novgorod and Pskov, and on May 10 it was heard not far from Leningrad.

These examples show us that by the existing large network of phenological observation points in the U.S.S.R. one can get results of great general interest. But incomparably more generalised and more interesting results could be obtained from the phenological observations if they were conducted in the same manner and with the same objects also in western Europe, so that diagrams could be traced covering the whole continent. For this purpose the programmes of phenological observations in the various countries, as also the methods of observations, must agree in general characters.

It seems to us that the best way for establishing such an agreement between the observations of different countries would be the organisation of an International Congress of Phenology, or of a special Section of Phenology at the next International Meteorological Congress. Such a gathering of specialists could discuss and fix the most appropriate list of objects for observation in every country, and it could elaborate also the best methods of observation, study, and publication of phenological phenomena.

Only by international agreement and co-operation can phenology—this link connecting biology and meteorology—be promoted to further development.

Relative Intensity of X-ray Lines.

THE development of the theory of atomic constitution has made measurements of the intensity of lines in X-ray spectra very important. Estimates of relative intensities of X-ray lines have hitherto been attempted by means either of the ionisation chamber or the photographic plate. Owing, however, to the lack of precise knowledge of the relative sensitiveness of these methods for different wave-lengths, the comparison of intensities of lines which differ in wave-length has involved a considerable uncertainty. To overcome this difficulty, absolute measurements of the energy of X-ray lines based on the bolometric method have been attempted by several workers. Since the wave-lengths used lie on the short wave-length side of the bromine *K*-absorption edge, the sensitivity curve for the photographic plate obtained in this way cannot be applied to measurements of the relative intensities of the *L*- and *M*-series of most elements. To obtain the sensitivity curve in this region, we have exposed plates to X-rays from different metals excited under conditions which can be discussed on the basis of the theory of X-ray production.

In a vacuum spectrograph of the Siegbahn type the four faces of an anticathode, which were covered with sheets of iron, cobalt, nickel, and copper, were exposed in succession by turning the anticathode from outside. The X-ray tube was run off a high tension transformer with a rectifier under constant working conditions, the effective value of the applied voltage being about 20 kv. The vacuum was maintained by a mercury vapour pump working continuously. To make our result as free as possible from accidental errors, especially those which might arise from a variation of the electron emission of the filament or of the vacuum in the tube, a large number of photographs was taken on the same plate, the sequence of exposure of the faces of the anticathode being varied. The blackening of the plate was measured by means of a Moll microphotometer, and relative values of the maximum blackening for the K_α and K_β lines of the four elements were obtained.

In order to utilise the information contained in these measurements for comparing intensities, we have made use of the following theoretical expression for the intensity of characteristic X-ray lines deduced by Rosseland (*Phil. Mag.*, vol. 45, p. 65, 1923):

$$F = Ci\frac{Nl}{V^2}\left\{\frac{V-V_0}{V_0} - \log\frac{V}{V_0}\right\}\nu,$$

where i is the current through the tube, N the number of atoms per unit volume of the anticathode, l the range of the cathode rays in the anticathode, V the applied voltage, V_0 the critical voltage for the excitation of the line under consideration, ν its frequency, and C a quantity which has the same value for homologous lines of the spectra of different elements. In this equation the value of l was obtained by interpolation from Schonland's results (*Proc. Roy. Soc.*, 108, p. 187, 1925) on the dependence of l on atomic number for various voltages. Although in the deduction of Rosseland's formula certain assumptions are made which are only fulfilled if the velocity of the cathode rays is large compared with the velocity ascribed to the electrons in the atom, this formula can be shown to account closely throughout the range of our measurements for the dependence of the intensity of X-ray lines on the applied voltage as determined by Wooten (*Phys. Rev.*, 13, p. 71, 1919) and Unnewehr (*Phys. Rev.*, 22, p. 529, 1923). It is therefore reasonable to expect that this formula will also hold with an approximation sufficient for our purpose as regards the variation of the intensity of X-ray lines with the critical voltage and the other factors which depend on the element.

On this assumption we obtained for a given photographic plate and crystal in the spectrograph a curve of the relative blackening as a function of wave-length. We were thus able to compare the intensities of the lines in the *L*-series of tungsten. For example, we found

$$L_{\alpha_1} : L_{\alpha_2} : L_{\beta_1} = 100 : 10 : 33$$

as the relative intensities corresponding to our experimental conditions. Since the critical excitation potentials for these lines are not quite the same, the relative intensities will depend on the applied voltage.

Correcting for the difference in the critical potentials by means of Rosseland's formula we obtain

$$L_{\alpha_1} : L_{\alpha_2} : L_{\beta_1} = 100 : 10 : 43 .$$

as the intensity ratio to be expected for an applied voltage very large compared with the difference of the critical potentials.

It is of interest to compare this result with the intensity relations of optical spectra. For the lines ***np-md*** of the alkalies, which have a formal analogy with the above X-ray lines, one would expect 9 : 1 : 5[1] (100 : 11 : 55) Here the measurements in Utrecht have given results agreeing with the theory. Although there is a close resemblance, it seems that our values differ from this ratio by more than the experimental error which we estimate at 5 per cent. Such a deviation is, however, not unexpected, since the theoretical result is only strictly valid so long as the frequency difference of the lines is very small compared with their frequencies. While this condition is fulfilled in the case of the doublets ***np-md*** of the alkalies, we meet in our case with a frequency difference of 15 per cent. which can scarcely be considered to be small.

We hope later to publish an account of the experimental details and of further measurements.

The Convection of Light by Moving Matter.

IN the paragraph under the above title, in NATURE of December 26, p. 948, a new question is put forward quite distinct from the discussion of Einstein's theory, dealt with in my unpublished letter of November 5, to which it refers.

The writer of the note, having noticed that I do not belong to that multitude who blindly follow Einstein, seems to conclude that I am of the Einstein-antagonist party, all of whom aim more or less to return to older ideas Even a scientist of well-deserved universal repute, such as Prof. Lenard in Berlin, in his polemic and anti-Einstein pamphlets, which have been reprinted many times, only proposes older theories in a somewhat modified form. But is that generally existing conformity a valid excuse to attribute to me what as a matter of fact is only the impression of the writer of the note ?

It obliges me to state emphatically that there is not the least essential connexion between the writings of all those Einstein-antagonists and my papers. I challenge the writer to point out in my papers (*C.R*, vol. 175, 1922, p. 574, and *Phil. Mag.*, Ser. 6, vol. 49, 1925, p. 579) a single word which may be interpreted as my advocating a return to older electromagnetic theory.

According to the paragraph, my " deduction is not entirely free from ambiguity, in so far as equation (11) in his earlier and more fundamental paper leads at once to the expression $\mu'_w = \mu + A(n' - n)$. . . . For A, which is a constant of integration, M. Menges puts $(\mu - 1)/n + d\mu/dn'$."

As to this, I can only say that neither the reasoning nor the formulæ is to be found in my papers.

My equation is :

$$\frac{d\mu'_w}{dn'} = \frac{\mu'_w - \mu}{n' - n}.$$

This is not given in NATURE. It is immediately obvious that the expression presented in NATURE as the solution of my equation is incorrect. For it may be written :

$$A = \frac{\mu'_w - \mu}{n' - n},$$

which, as a solution of my differential equation, is absurd.

Within the scope of a letter, it is quite impossible to explain my new formulæ fully. I must refer the reader to my books "Nouvelles vues Faraday-Maxwelliennes" and its "Supplément" (Gauthier-Villars and Co., Paris, 1924). There he may see that my mathematical deduction is quite free from ambiguity and undoubtedly correct, and that it leads to the true solution of the question. He will find also that it is by no means by returning to, but, on the contrary, by radical departing from older electromagnetic theory, that my new results are obtained. My new formulæ and new insight in electromagnetism, confirmed by experiment, then leads to the result that Einstein's theory is inadmissible.

CHARLES L. R. E. MENGES.

The Hague,
December 30.

M. MENGES seems to have misunderstood the drift of my notice, which was intended as a *critical review*, not an *abstract*, of his two published papers, without any direct reference to his unpublished covering letter at all. I am not conscious of having attributed any views respecting Einstein's theories, either for or against, to M. Menges, whilst the references to Newtonian principles and the older electromagnetic theory followed naturally from the *Phil. Mag.* paper and its references to the books of Jeans and H. A. Lorentz. I added the reference to v. Laue's paper for the sake of completeness, for it shows that the experiments of Fizeau and Zeeman do not lead to the result that Einstein's theory is inadmissible, as M. Menges states in his letter.

The paragraph of which M. Menges complains is a criticism of his solution (12), not a reproduction of his method of deriving it from his equation (11), for he gives no details in his papers. If we write $n' - n = x$, $\mu'_w - \mu = y$, n and μ being constant parameters, (11) reduces to $dy/dx = y/x$, which is the familiar differential equation of a plane pencil of straight lines through the origin. Its *general* integral is $y = Ax$, where A is the constant of integration ; I fail to see the absurdity of this well-known solution, for its verification is immediate. The point of my criticism is that M. Menges' solution (12) is only a *particular* integral, obtainable of course by choosing a particular value of A ; in the papers specifically referred to, M. Menges gives no sufficient reason why this particular integral should be selected rather than any other. It may well be that good reasons are given in his book, but I have not had access to it My wording no doubt is liable to misconstruction : it would have been better to write : " We can obtain M. Menges' solution (12) by putting for A the particular value $(\mu - 1)/n + d\mu/dn'$."

THE WRITER OF THE NOTE.

Mullet as an Enemy of the Oyster.

DURING the past summer large numbers of oysters carrying larvæ were examined in the Plymouth laboratory, and in order not to waste the larvæ, batches were thrown as food into an aquarium tank containing anemones, sea-cucumbers, small fishes, and other smaller marine animals. After throwing the larvæ into the tank, the animals being fed were watched, and it was found that a small school of small grey mullet (*Mugil chelo*) in the tank came rapidly towards the clouds of larvæ and greedily ate them up. These mullet soon became accustomed to being fed on larval oysters, and quickly appeared from remote portions of the tank when larvæ were thrown in.

---

[1] D. Coster and S. Goudsmit, *Naturwiss.*, 13, p. 11, 1925, A. Sommerfeld, *Ann. d. Phys.*, 76, p. 284, 1925.

The manner in which the mullet obtained the larval oysters from the water is remarkable for a fish. The fishes entered the cloud of oysters and while remaining poised or practically still, very rapidly drew water in at the O-shaped mouth and expelled it out through the gill-slits, by using the walls of the oral cavity as a pump. The action is an accentuation of the ordinary breathing mechanism. Obviously also the water passing into the mouth was sieved, as the cloud of larvæ in the water soon cleared on the advent of a number of the little fishes.

Cunningham ("Marketable Marine Fishes," p. 335) records the presence of minute molluscs in the stomachs of mullet, and Day ("British Fishes," i 229 and 234) points out that there is "a filtering apparatus in the pharynx which prevents large and hard substances from passing into the stomach, or sand from obtaining access to the gills"

The mechanism which prevents sand from passing the gills is not unlikely used for filtering off plankton organisms, such as oyster larvæ, as food. It is the more probable that young mullet and to some extent older fishes are partially general plankton feeders, since Day also records the occurrence of minute Crustacea in the stomachs of mullet.

Since mullet abound in some of our estuaries where oyster beds occur, it is practically certain that those and also other small fishes take a toll on oyster larvæ, as Lebour (*J.M.B.A.*, 12, 3, p. 464) has shown that young sprats may do. In a recent publication ("The Story of the Oyster," *Australian Museum Magazine*, ii., 1925) T. C Roughley states, without, however, giving any details, that Australian mullet destroy oyster larvæ; thus it would appear that the mullet family in different parts of the world feed in a similar way.

Although there can remain little doubt that young mullet are enemies of oyster larvæ, the critical test would be derived from the examination of stomachs of fishes taken over or near an oyster bed in summer, and especially in the period preceding new moon Such material will, however, not be easy to obtain.

Absorption and Resonance Radiation of Excited Helium.

PASCHEN in 1914 published results of experiments on absorption and resonance radiation in weakly excited helium. A more extensive investigation is being made of absorption in excited helium, and results have been obtained indicating absorption of the following lines:

5875 3889 5016 6676
4471 3187 3964 4921
4026 3614

It was observed that 3889 was very strongly absorbed, and it was decided to attempt to detect resonance radiation. Light from an intense capillary was focussed by means of a cylindrical lens along the axis of the resonance tube. This served as a strong source of monochromatic radiation of wave-length 3889 Å.U. The resonance tube was focussed, end on, on the slit of a quartz spectrograph adjusted with a wide slit. A series of three photographs was then taken, namely:

1. With the weakly excited resonance tube alone and the light from the capillary screened off.
2. With the resonance tube as in the first exposure and the light from the capillary incident on the resonance tube.
3. With the resonance tube off but the light from the capillary still focussed as in the second exposure.

Examination of the plate showed a barely detectable trace of scattered light. Under the influence of the monochromatic radiation from the capillary, a great increase of the intensity of the radiation of wave-length 3889 Å.U. from the central portion of the resonance tube, on which the light from the capillary was focussed, was observed. Since this was not due to scattered light, as was proved by the third exposure, it must have been due to resonance radiation from the weakly excited helium

This result appears to prove beyond doubt the possibility of obtaining resonance of the 3889 line in weakly excited helium. A more detailed account of the work will appear shortly.

Allotropy of Chromium.

CHROMIUM prepared by a special method was found to have certain peculiar properties. This fact has led us to make an X-ray examination of the structure of this material, which has revealed the fact that this specimen of chromium was a mixture of two allotropes. Besides a much smaller quantity of the normal body-centred cubic modification, the predominating structure consisted of a form not previously described.

The atoms are arranged on two hexagonal lattices, and form a structure which is almost hexagonal close-packed, the axial ratio c/a being 1·625 instead of 1·633, the ideal ratio for the close-packing of spheres. The distance between neighbouring atomic centres is 2·714 and 2·705 Å U. Below are tabulated the readings obtained from the film and those calculated for a structure of the above type:

Radiation.	Interplanar Spacings in Angstroms.		Reflecting Planes.	Intensity of Lines.
	Observed.	Calc		
β	2·204	...	0002	Very weak.
α	2·346	2·331	$10\bar{1}0$	Weak
β	2·064	...	$10\bar{1}1$	Weak.
α	2·202	2·203	0002	Medium.
α	2·068	2·074	$10\bar{1}1$	Very strong.
α	2·034	...	(110) [1]	Medium.
α	1·608	1·608	$10\bar{1}2$	Very weak.
α	1·358	1·357	$11\bar{2}0$	Weak
α	1·248	1·246	$10\bar{1}3$	Medium.
α	1·177	1·175	$20\bar{2}0$	Strong.

[1] This corresponds with the (110) spacing of the body-centred variety of chromium.

Further work on this subject is in hand to determine the conditions under which the two allotropes are formed.

The X-ray examination was undertaken by us at the Physical Laboratories of the University of Manchester, by the kindness of Prof. W. L. Bragg.

X-rays in Industry.[1]

By Dr. G. W. C. Kaye, O.B.E.

THERE are few more stimulating pages in the history of scientific endeavour than those which record progress in the field of X-ray investigation and application.

Physical research has spread itself over 60 octaves or more of electromagnetic waves which are now known to stretch without break from wireless waves 25 miles or more in length through heat waves, visible light waves, ultra-violet waves, and X-rays to gamma-rays of wave-lengths of the order of a ten-thousand-millionth of an inch. In this gigantic gamut of natural activity that group of radiations encroaching into and extending some thirteen octaves beyond the ultra-violet, and possessing wave-lengths ranging from about 5×10^{-6} to 5×10^{-10} cm., is now generally styled X-rays. Of these thirteen octaves, ten are extremely absorbable, but the remaining three possess those remarkable powers of penetrating matter which made Röntgen's discovery so arresting and monumental when it was announced exactly thirty years ago. If we include the gamma-rays of radium, this gives us a total of nearly six octaves of radiation with which the science of medical and technical radiology of the present day does its work.

The differential absorption of X-rays by matter of different densities (which makes the work of the medical radiologist possible), and the diffraction of X-rays, are phenomena which have been turned to account in the industries and arts in a diversity of directions. At the outset mention should be made of the dangers arising from X-rays. These are well known and have caused many casualties in the past. They can, however, be wholly avoided by common-sense protective measures which consist in the main of interposing lead sheet or the like, properly disposed and sufficiently thick, between the X-ray tube and the operator. The reports of the X-ray and Radium Protection Committee should be consulted for details by which complete safeguards can be secured.

RADIOGRAPHY.

One other practical precaution arises in industrial radiography, and that is the necessity for taking account of the scattering of the X-rays. Three things may happen to a beam of X-rays when it passes through a material. Part of it emerges undisturbed and undeviated, and outlines the shadow picture on the photographic plate. Part of it is absorbed with the liberation of characteristic X-rays and electrons. The rest is scattered or dispersed, which is equivalent to stating that, while the rays are not altered in quality or but slightly so, a considerable proportion of them have their direction altered to a greater or less extent. In some cases it is estimated that, of the energy received at a point well within or beyond a mass of material, the fraction arriving by devious routes may be equal to or several times greater than that by the direct route. This proportion may be lessened by narrowing the width of the beam of incident rays, but the size of the aperture is usually prescribed by the size of the object and, in general, the X-ray beam does not approximate to a pencil. Scattering thus produces a sort of halation or fogging of the main image on the photographic plate. The effect may be troublesome enough, even with lesser thicknesses, to impair definition in the absence of suitable precautions, but increases to such an extent with greater thicknesses as to render the method nugatory or nearly so.

Many of the various applications of radiography to industry have come about owing to the fact that the method does not injure the specimen in any way. Further, it provides in many cases the only means, independent of human judgment, of detecting concealed defects in a material or of scrutinising in a structure or sealed enclosure the disposition of component parts which are hidden from view. Incidentally, the mere existence of the method is not without its moral value as regards workmanship. Radiography is, of course, inoperable in those cases where the shape of the object prevents the right disposition of X-ray tube and film.

The X-rays found little effective scope in industry until the invention of the Coolidge tube, which permitted the utilisation of high voltages with standardised procedure. Experience differs as to the sensitiveness of the method, but, depending on the area of the inclusion, probably a variation in density equivalent to 2 to 5 per cent. of the thickness is necessary to be detected on the photographic plate. These figures require to be increased for fluoroscopy, but much depends on the luminosity and on the visual acuity of the observer. Definition is, of course, dependent, among other things, on the size of the focal spot in the X-ray tube. If a body has tapering edges, this will normally result in a nebulous radiographic outline. Exposures naturally depend on the conditions, and may vary from a few seconds to an hour or more. Stereoscopic radiography is sometimes useful in estimating depth.

If the intrinsic value of a specimen is low, or if "mass inspection" is contemplated, then visual inspection with a fluorescent screen is the only practical policy. It is not always satisfactory, but the more expensive and protracted process of photography has to be justified by the value of the specimen, or the importance of the job for which it is intended, or the desirability of confirming the fluoroscopic diagnosis by a permanent record. For some industrial purposes Dauvillier employs an exploring ionisation chamber filled with xenon, the ionisation currents being readily measured by a galvanometer.

The shape of the specimen may be such as to emphasise the evils of scattered radiation. If the object is continuous, with one side flat, there is no difficulty; for the flat side can be brought into close contact with the photographic plate. The same end can be achieved with bodies of regular shape, such as cylinders or spheres, by resting them in closely fitting solid metal "cradles" with flat bases. If the body is irregular in contour, something may be done by filling up pockets or hollows with wax or plasticene and placing a "mask" of lead or lead powder round the specimen. With hollow bodies a film may sometimes be placed inside and sprung against the interior face, though parallax is often exaggerated. In all cases the photographic plate or film should be backed and framed with lead foil.

---

[1] From a public lecture delivered at the University of Leeds, November 30.

It should be realised that, while X-rays have proved of considerable value in many directions, their use in radiographing steel is limited at present. While both in Great Britain and America X-rays have been detected photographically after passing through 4 inches of steel, the result has little or no practical value. The present practicable limit is more nearly 2 inches for photography and less than half an inch for fluoroscopy. Incidentally, the corresponding limit for solid masonry is about a foot.

The quality or mean wave-length of the X-rays used depends on the requirements. For very transparent objects X-rays excited by fifty thousand volts or less may suffice. For the more opaque materials we require rays excited by up to 200,000 volts, which is as near to the present upper limit as any present-day X-ray tube will stand. Approximately double this voltage will be required to test so much as 6 inches of steel. The electrical engineer can, of course, generate such voltages, but an X-ray tube has yet to be designed which is capable of turning them to account. The task is not proving easy of solution, and the fact has a bearing on the possible extension of radiometallography to heavy engineering. With such high voltages the scattering effect may be somewhat reduced, and the attendant dangers could doubtless be countered if the results warranted the expense.

Within its limitations, however, radiography is very sensitive; for example, fine tool or mould marks and similar surface irregularities are frequently displayed in radiographs. Blowholes in castings show up as light spots. Cracks are occasionally revealed, though, if they are filled with material of density not very different from its surroundings, or if the cracks are fine or tortuous (hair cracks), the method normally fails. A negative result does not, in fact, afford a positive answer. Inclusions of sand, etc., are registered as cloudy, indefinite areas. The method has been proved to be of value in suitable cases for checking up steel castings and so preventing the machining of defective castings.

If the specimen is of large area, such as a turbine disc, to radiograph the whole disc is a costly and protracted operation which has, however, on occasion been carried out in its entirety in Great Britain. But normally in such cases the X-ray method would be used only when the material is already under suspicion by the use of other tests.

X-ray photography of steel welds has been used successfully for thicknesses up to about 1 inch. Welding is discredited for some purposes, for it is easy to scamp such work, but the X-rays are a somewhat severe critic in displaying blisters, blowholes, and lack of bonding. Skilled experience can usually say whether any imperfections indicated in the radiograph are sufficiently serious to disqualify a weld for its purpose. The method will not, however, indicate a common defect of welding—the burning of the adjacent metal.

The X-rays have become a useful adjunct in the photography of a variety of subjects in the laboratory and in the industries. The manufacturers of electrical insulators—ebonite, built-up mica, fibre, paper—find the X-rays useful for detecting the presence of metallic particles, particularly if a high-grade product is desired. Fibre is frequently made from pulped rags and so may contain foreign metallic matter. Feminine labour has been occasionally responsible for the presence of hairpins in the finished product.

The centrality of the core of a heavily insulated electric cable can be tested by this means. In such a case as this, to secure both a sharp outline of the opaque core as well as clear detail of the more transparent insulation, a good plan is to make the exposure partly at a high exciting voltage and partly at a low voltage. The soundness of steel balls intended for ball bearings; the differentiation of lead-glass from soda-glass stems of clinical thermometers—now a routine test at the National Physical Laboratory—the centrality of the cores of golf balls; the test of the fit of a new shoe on the foot as now met with in many shoe shops; the nature of certain defects in artificial teeth; the proportion of ash in samples of coal, are among recent examples of the use of the method.

Aircraft materials afford scope for the X-rays as a testing agent. Aluminium alloys are very transparent, and so lend themselves to radiography, while if steel is used, its greater trustworthiness is offset by the necessity of keeping the weight down. The main difficulty, in fact, with aircraft components is usually their shape rather than their thickness. Timber offers no difficulty, of course, and the use of X-rays in this connexion, more particularly as regards aeroplane parts, was demonstrated during the War.

If a material is very transparent, its opacity may sometimes be increased much as a medical radiologist uses bismuth meals to watch processes in the alimentary canal. For example, the Dunlop Research Laboratory, by previously impregnating selected canvas threads with lead chromate, was able to test whether the stretch during the successive processes of manufacture of a tyre was within the limits tolerated by the yarn. Similarly, if it is desired to watch the behaviour of glued joints or splices while under stress, the radiography is facilitated if a little lead salt is added to the glue.

X-ray photography is at times particularly useful for displaying the construction of apparatus, the interior of which is hidden from view by thin metal or other opaque container. Among examples which may be cited are the counting of the turns of wire in a coil heavily covered with insulation; the details of the design of opaque vacuum pumps and radio valves; the interior detail of opal-glass electric lamps; the construction of selenium cells; the internal diameter of metallic tubing; and the interior construction and accuracy of assembly of explosive devices—this last by the Research Department at Woolwich Arsenal.

In quite another direction radiographs recently taken in Chicago of Egyptian and Peruvian mummies showed that rickets, bony tumours, pyorrhœa, caries of the teeth, were common conditions of disease, as nowadays. It was further found possible to gather something definite about the age and sex, and the nature of any injuries received. A recent attempt to X-ray the mummy of Tutankhamen was nullified mainly by the heavy gold "armouring" of the body.

Finally, one other application of radiography may be referred to. As is well known, the forging of valuable pictures and antiques has always been a flourishing industry. One estimate puts the number of Rembrandts in existence at four to five thousand, yet, so far as is known, Rembrandt painted about 700 in his lifetime. We know that Sheraton had a little shop and did most of his work himself with only occasional help from a few expert artisans, but the amount of Sheraton furniture in existence belies the truth of this.

The X-rays have shown that they can sometimes usefully supplement the tests which are commonly resorted to for detecting fraud in old Masters and antiques. A radiograph will sometimes reveal constructional or other detail sadly out of tune with the reputed period. In the case of pictures or panels, the X-rays may give instructive information on the pigments which, in general, are more opaque in old pictures than in new, on the priming, which is commonly more opaque in new pictures than in old, and on the canvas, wood, or other surface painted on. Thus it happens that in the case of an old painting the X-rays can sometimes be employed as a means of detecting alterations or restorations or of identifying a modern fake.

Radiography could similarly be used to establish the identity of originals of modern pictures or panels, forgers of which are therefore not prevented from simulating closely the canvas, wood, and pigments. But in a radiograph the fine details of the canvas, or of grain and knots in the case of wood, are so characteristic as to be impossible of exact copying. If such records were normally taken, the method would also be of service in differentiating between the original and the copies painted by the artist himself. Furthermore, tentative detail ultimately painted out is sometimes revealed in the original painting which naturally is not repeated in the copies.

X-RAY DIFFRACTION

From Laue's momentous discovery in 1912 of the diffraction of X-rays, the science of X-ray spectrometry has grown to great proportions. The main developments deal with emission and absorption spectra, with crystal analysis and with the structure of atoms. Naturally, with the growth of the subject, special apparatus and technique have been developed.

In optical spectra the number of lines peculiar to an element are frequently numerous and their numerical relations complicated. X-ray spectra, on the contrary, are noteworthy for their simplicity, the number of lines characterising an element being relatively few, readily recognisable, and measurable with a precision not inferior to that which obtains in optical spectra. Moseley's great discovery in 1913 established a simple proportionality between the atomic number of an element and the square root of the frequency of a characteristic radiation or of an absorption limit. Moseley's law holds for all the known elements, and so it is possible to interpret new spectral lines with ease. It was by X-ray spectrometry that the element hafnium was discovered in 1923; and only recently Nonnack and Tacke announced the discovery by X-ray analysis of two new elements which they called masurium and rhenium. Thus 89 out of 92 elements are now known, and the spectral lines of the missing three elements (Nos. 61, 85, 87) are predictable with certainty.

X-ray absorption spectra are very simply obtained by passing a pencil of X-rays through a sample of the matter and examining the transmitted beam by a crystal spectrometer. The X-rays should be excited by a suitably high voltage. It is best to have the substance in finely powdered form deposited on, say, paper. Very little material will suffice if the absorbing screen is placed at the slit of the "collimator." Solutions can also be tested, though not so readily. The method is specially applicable to all elements with a strong *K* absorption band, *i.e.* the iron group and heavier elements. For the elements of high atomic number the *L* band is also convenient. In the case of mixtures of adjacent elements the several absorption bands may tend to obscure one another, and for this reason the method excels in detecting traces of heavy elements in light elements.

Emission spectra are conveniently excited by mounting the material on the face of the target of an X-ray bulb and applying a suitably high voltage. In such spectra every element present is recorded with an intensity which depends only on its concentration and is independent of the presence of any other elements with which it may be mixed or combined. Such intensities are measured with a microphotometer. The method thus enjoys great advantages over optical spectroscopy. The test is a very sensitive one and, although not suitable for the very light elements, has found commercial application in analysis of the platinum group of metals and the rare earths. An alternative method, though not so effective, is to bombard the test material with X-rays, as in Barkla's original method of exciting characteristic X-rays. This can be readily made the basis of a method for analysing mineral salts.

The aim of X-ray crystal analysis is to determine the grouping of the atoms and molecules in the crystal unit, and so to account for the properties of the crystal. There are three main experimental methods:

(*a*) Laue's method, in which a narrow pencil of heterogeneous rays is passed through a single crystal.

(*b*) The Hull-Debye-Scherrer method, where homogeneous rays are passed through a thin rod of crystalline powder.

(*c*) The Bragg spectrometer method, in which a "slit" of homogeneous rays is reflected from a single crystal.

Many variations in the technique of these methods have been developed, some of which are becoming of industrial importance. For example, the Laue method may be arranged to test the general orientation or symmetry of crystal aggregates, in which case homogeneous rays are advantageous. The Bragg method is also applicable to a conglomeration of minute crystals. In many of these methods the specimen is kept in continual rotation or oscillation (de Broglie).

Our knowledge of the atomic structure of the solid state of matter owes more to X-ray analysis than to any other means. For example, most chemical elements, including solidified gases, have been shown to crystallise in the cubic or hexagonal system. Already nearly half the elements have been examined, including those allotropes which can arrange themselves in more than one kind of space lattice. As regards alloys—solid solutions and intermetallic compounds—the

X-rays have thrown light on and tested the truth of the existence of the several phases of steel and other alloys which metallurgists had differentiated by other means. The method has also indicated the atomic features which go hand in hand with ductility, hardness, etc. It has also been shown that in a solid solution of two elements the replacement of one atom by another is effected by substitution in and distortion of the lattice and not by interstitial insertion (Owen and Preston at the National Physical Laboratory). Other points which have been worked on are the effect of annealing, tempering, rolling, or other working; the mechanism of deformation and slip in metals; and the general shapes and sizes of atomic domains.

By the use of X-rays Sir William Bragg has shown that a diamond has an atomic bonding perfect in its symmetry and so possessing intense hardness. On the other hand, graphite (another variety of carbon) with unsymmetrical atomic linking, with weak linking and greatest separation between cleavage planes, is a good lubricant. So-called amorphous carbon is found to consist of minute graphite crystals. The fragility of annealed tungsten lamp filaments is explained by the gradual transformation to a number of single crystals of large dimensions.

The X-rays have demonstrated that almost every solid substance in Nature shows crystalline form, including such apparently amorphous materials as rubber, cellulose, soap, leather, bamboo, and talc. Müller and Shearer have shown that the fatty acids give characteristic spectra which enable them to be identified in mixtures. This work was done at the Davy Faraday Laboratory where, under Sir William Bragg's guidance, the structures of many organic and inorganic crystals have been elucidated. Colloidal metals are shown to be made up of minute yet perfect crystals so small that they contain only a few score atoms. The molecular arrangements in thin metal and liquid films have been ascertained. In gold leaf, for example, the cubic crystals are found to have their cube faces parallel to the sheet. The Laue method has been used at the National Physical Laboratory to ascertain the crystal axes of jewel bearings. Within the last few months Dauvillier and Shaxby have ascertained the structure of pearls and shown that the Laue method, using homogeneous rays, affords a trustworthy and valuable criterion between the true natural pearl and the cultivated Japanese pearl, consisting of a thin pearly covering on a sphere of mother-of-pearl as a nucleus.

These are but a few of many examples which indicate that the several processes of X-ray spectroscopy are not only a valuable scientific tool for the physicist, but also that they are destined to play an important rôle in many industrial processes of the future. There are grounds for hoping that light may be thrown on the mechanism of such properties as magnetism, electrical and thermal conductivity, contact and thermal electromotive forces, dielectric capacity, fluorescence, the various types of elasticity, cohesion, diffusion, adsorption, etc.

Mineral Industries of the United States during the War.

THE mineral resources of the United States are of primary importance, for in 1915 that country produced 40 per cent. of the world's output of coal, 40 per cent. of its iron ore, 32 per cent. of its lead and zinc, 60 per cent. of its copper, and 66 per cent. of its petroleum. Since then, some of these proportions have increased. The data for the history of the mineral development of the United States during the War have now been issued in seven thick volumes,[1] which contain for each year the full record of the United States output of all important economic minerals, with shorter accounts of the contributions of other countries. The volumes consist mainly of compilations of mineral statistics accompanied by the statement of such geological and economic facts as are necessary to their interpretation. In each volume some chapters, in addition to the annual statistics and record of the year's development, contain a general review of the subject with reference to the current literature and geological descriptions of the chief mining fields. These monographic chapters include those on chromite by J. S. Diller, on graphite, with interesting accounts of its mining in Ceylon and Madagascar, by H. G. Ferguson, on molybdenum by F. L. Hess, on potash by W. B. Hicks, on American utilisation of peat by C. C. Osbon, and on quicksilver by F. L. Ransome. In view of the importance and variety of the American yields, the especially important sections are those dealing with coal, petroleum, and the five metals which are so closely associated that they are recorded together—gold, silver, lead, copper, and zinc.

We find in these volumes, in addition to the record of the normal development of the mining industry, an account of the more sensational temporary effects of the War, which were often bewilderingly unexpected and contrary. Prices rose and fell in a manner that was at the time inexplicable, and in some cases is still obscure. The answer may be simple, though not obvious at the time; thus, although cadmium is more expensive than tin it was used in solders as a substitute, so that tin might be reserved for purposes for which it was indispensable. Some of the uses to which cadmium was put are still unrevealed, and Mr. Siebenthal, the author of the chapters on that metal, reports that a German firm in 1913 advertised for the purchase of unlimited supplies, and refused to answer inquiries as to the purpose for which it was wanted. It was certainly used in Germany during the War as a substitute for tin, but other uses by the belligerents on both sides have not yet been revealed.

The War, by its increased demands for metals, helped some branches of mining, but hampered others; thus the unlucky antimony miners of China, who produce the bulk of the world's supply, suffered both from the fall in price of their product and from the rise in the price of silver, which added to their working costs. In the case of some metals a fall in prices appeared to encourage production. This anomaly is now explained by the feverish prospecting in consequence of the sudden increase in the demand. Thus in the zinc fields of Oklahoma it is estimated that ten years prospecting work was done in two years; and ore had to be produced and sold at any cost to repay the expensive development work, and thus the mines had to empty their reserves during the subsequent slump in prices. The anxiety as to the shortage of molybdenum in the early part of the War was easily allayed by the United States, where it was known to occur in many districts; the chief producer had been Arizona, but the demand was satisfied by the output from the colossal deposits of fractured granite yielding about 0·8 per cent. of molybdenite at Bartlett Mountain near Leadville, Colorado.

Washington: Government Printing Office.

In spite of the War troubles, many of the American mining fields continued their normal progress. Thus the goldfields of California, in spite of seventy years of production, still have mines working in five of the counties along the great Mother Lode; in 1918 they yielded no less than 1,015,509 short tons of gold ore of a value of 4,334,061 dollars, or an average of 4·268 dollars per ton. The total yield was smaller owing to the War conditions and not to the exhaustion of the ore, and some of the mines that closed down are expected to reopen when costs become normal. The placer mines of California are worked successfully both by hydraulic sluicing and dredging, and it would be of interest if the yield per cubic yard and costs of working were stated. For Alaska these figures are given, showing that the dredges are working there at the high cost of about 2*s.* 6*d.* per cubic yard; the amount fell owing to the higher costs. Of the Alaskan placers 574 of them were at work during the summer and 153 in the winter; but the lode mining is increasing and in 1918 yielded 29 per cent. of the output. The great Homestake Lode of South Dakota, famous for the large scale of its operations, has still vast reserves of ore. Between 1875 and 1918 it has yielded 160 million dollars of gold with a profit of 41 million dollars. The output of ore in 1918 was 1,628,000 tons, but the dividends, owing to higher costs, fell one and a half million dollars.

The United States still maintains its supremacy in copper production, and on opening these volumes it is natural to turn at once to the sections which show the conditions at the Calumet and Hecla Mines of Lake Superior. They work three "lodes," as they are called to satisfy American mining law. The famous conglomerate which was the most remarkable ore from this field is nearly exhausted; the working of the amygdaloids is increasing, and the mines obtained 67 million pounds of copper during the year 1918, at a total cost of 21·65 cents per lb. The prolific field of Butte, which, mainly from one mine, the Anaconda, for years supplied 60 per cent. of the world's output of copper, has had in recent years a less prosperous time owing to the competition of large bodies of low-grade ore in the south-western States; but the yield from Butte in 1918 was still more than 313 million lb. of copper ore worth nearly 80 million dollars, in spite of the fall in price of the metal from the previous year. An especially interesting development announced is the reopening of the lower levels of the famous Comstock Lode in Nevada. Their closing thirty years ago by floods of superheated water is one of the best known and most instructive tragedies in the history of mining. The water has now been lowered by electric pumps through the Sutro Tunnel, world famous for its evidence as to the geology of the Comstock Lode; and good ore has been worked at 2900 ft., and some ore found at the depth of 3100 ft.

Tin remains the one metal in which the United States output is practically negligible. In 1918, in spite of the search for tin stimulated by its high price, the output amounted only to 69 short tons, mostly yielded by the gravels of Alaska with a little from South Dakota and Carolina. The report on tin is illustrated by one of the many interesting maps showing the distribution of mining through the world; but this map appears to suggest that the Australian output of tin is in New South Wales, and the figure should have been over Tasmania.

Amongst the non-metallic materials, the normal development has continued the remarkable increase in American cement production, which is now nearly all of Portland cement. A peat industry has been established in recent years; its delay was no doubt due to the abundance of coal. The peat deposits of the United States are widespread through the north-eastern and north-central States from Minnesota to Maine, and the oft-expressed belief that peat cannot be formed in the tropics is contradicted by the large supplies known in Florida and beside the Gulf of Mexico. The bulk of the peat in the United States would appear to be a result of glacial conditions, and it is attributed to accumulation in the lakes, pools, and marshes left by the last glaciation. Peat is used mainly in the States for the manufacture of bacterial fertilisers, and as litter owing to its power of absorbing stable fluids; but in 1918, owing to the higher price of coal and difficulties of transport, it was used as fuel for the first time on an important scale in parts of the United States.

One of the most interesting developments of the non-metallic minerals during the War was that of potash. The agriculture of the eastern States of America was largely dependent on German supplies, and on their complete stoppage desperate efforts were made to utilise the local sources. It was found, however, that potash is not so indispensable as had been thought, and the view has since been expressed that the American farmers' faith in potash was a delusion inspired by the persuasive salesmen of the German Potash Syndicate. The urgent supplies of American potash were yielded by the Salt Lakes of western Nebraska; but it is recognised that they cannot be worked at post-War prices. The development of Searles Lake in California has been watched in Great Britain with especial interest; but the reports up to 1918 are of continued disappointments owing to technical and legal difficulties, which, it is said, are at length overcome and ultimate success there is anticipated. Some American igneous rocks contain huge quantities of potash silicates, but it seems doubtful whether they can be worked profitably in competition with the German supplies. The volume for 1918 enumerates many patents for the extraction of potassium from silicates; but these are not now regarded as hopeful, as the fall in price after the renewal of supplies from Germany led to a collapse in American production, and the closing of most of the potash mines.

Coal is dealt with at great length for each year, and the report condemns what it describes as the utterly wasteful methods of American coal mining. The chapters on petroleum record the intense activity of the period under review, which afterwards had a disastrous effect on the American industry. The efforts of 1918 are now ancient history in the swiftly changing conditions of the mineral oil industry, and it is interesting to read the predictions of 1918 with the information of six years later. It is remarked with satisfaction that the oil yield had been maintained in spite of the inherent difficulty of finding new pools, and it is suggested that California, after six years' production at its peak, must be prepared for a decline. The great success of the year 1918, in consequence of the active drilling, was in Texas; but that achievement was soon surpassed by the enormous increase from California, which produced a revolution in the American oil trade. In the report on 1915–16, confidence was expressed in the quick development of the oil shale of Colorado, but apparently nothing is said about that material in the later volumes, and the American output of shale oil was only begun in subsequent years.

By their wealth of compressed information and by the varied interest of the problems elucidated, these reports maintain the high standard which has made the series one of the chief works of reference in the history of the mineral industries of the world. J. W. G.

Solar Eclipses and the Eclipse of January 14, 1926.

THE rarity and striking character of total eclipses of the sun naturally predisposes astronomers to their study. Eclipses have revealed a remarkable feature in the movement of the moon, and successive observations are year by year increasing our knowledge of the sun's surface and surroundings. In the eighteenth century Halley, from the study of records of early eclipses, inferred a secular acceleration in the moon's motion. Twenty years ago Cowell confirmed this, and discovered a small secular acceleration of the sun's motion. His results have been further verified and amplified by Fotheringham. It has been shown by Taylor and Jeffreys that these results can be quantitatively explained by a slowing of the earth's rotation caused by the friction of the tides in certain shallow and constricted seas.

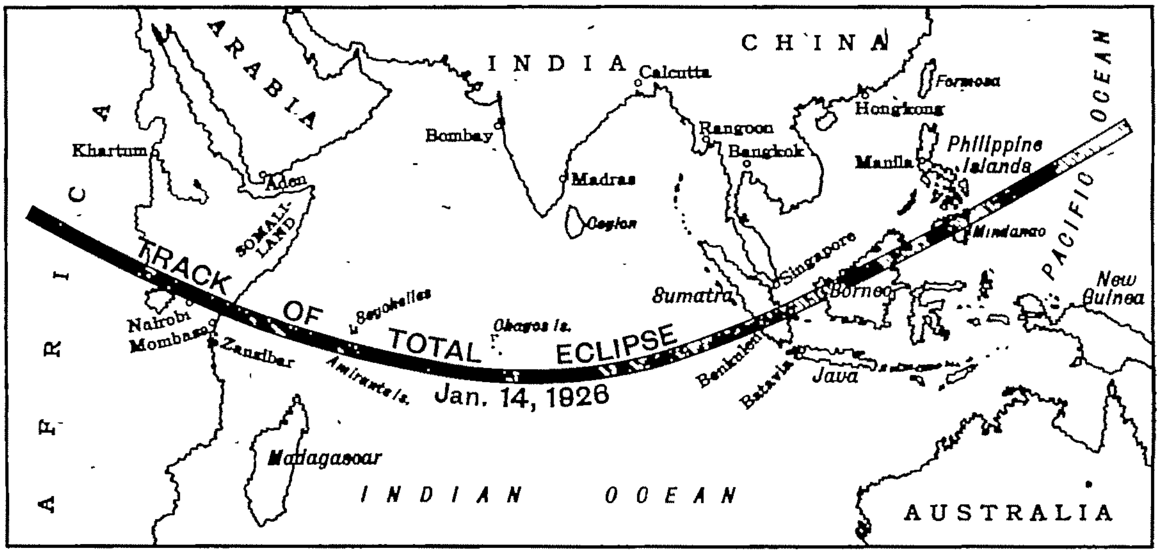
The observations of eclipses in the earlier part of the nineteenth century showed that the corona as well as the prominences belonged to the sun itself, and that it was not a halo produced in some way by the earth's atmosphere. The eclipse of 1868 led to the simultaneous discovery by Janssen and Lockyer of a method of observing prominences without an eclipse, and was a first stage towards the development of the spectro-heliograph. At the eclipse of 1870 Young, watching the diminishing crescent of the sun through his spectroscope, observed the reversal of the dark lines of the spectrum at the moment the eclipse became total. The existence of a green line in the spectrum of the corona near the iron line 1474*K* was also discovered. In course of time it was found that this line could not be attributed to any known element, and the name coronium was given to the substance from which it emanated.

Since this time the most important observations at eclipses have been made by photography. They have confirmed the fact, already shown by drawings, that the form of the corona changes in sympathy with the well-known cycle of the sun's activity shown by spots and prominences. But the main purpose of modern eclipse observations has been the elucidation by means of the spectroscope of the nature of the sun's surface and of the corona. One important exception is the verification of the bending of a star's light in passing through the sun's gravitational field, predicted by Einstein. British observers, taking advantage of the neighbourhood of seven bright stars in the eclipse of 1919, found that these stars showed, severally, displacements in accordance with the generalised theory of relativity. The result was confirmed in a more statistical manner by the American astronomers at the eclipse of 1922.

A great advance in the study of the constitution of the sun's surface as revealed at the instant at which the eclipse becomes total was made by Lockyer and Fowler in 1893. They found that the "flash" spectrum, as it is called, was not a mere reversal of the solar spectrum, but that many lines were "enhanced" in brightness, corresponding to differences found in the laboratory between spectra of the same substance obtained from an arc and from a spark. They amplified this by observations at the eclipse of 1898, and the striking differences between the "flash" spectrum and the permanent spectrum have been verified over a greater range of spectrum and in more detail at subsequent eclipses. These differences are now known to arise from ionisation of the elements, and Saha has shown what light they throw on the pressure and temperature at different levels above the sun's photosphere. In this connexion, the accurate determination of the heights above the photosphere which different elements attain is of importance. These heights have been determined from the lengths of the arcs of the "flash" spectra obtained by the use of an objective prism, but further research is needed.

These partially solved problems, combined with the desire to witness a very striking phenomenon, attracted a large number of astronomers from different countries to observe the eclipse of January 14, 1926. The track ran from the east coast of Africa across Sumatra to the Philippines (Fig. 1), and the maximum duration of the total phase was a little more than four minutes. An Italian expedition, under Dr. Horn d'Arturo, went to Somaliland. The British, French, German, Dutch, Australian, and several American expeditions chose sites in Sumatra, generally near Benkulen on the west coast, or the more readily accessible Palembang on the east coast. The telegraphic reports show different degrees of good fortune in the weather. The distribution of observers ensured good photographs of the corona. This is satisfactory, as in view of the relationship between the form of the corona and the phase of the solar cycle it is desirable that such photographs should be secured at all the rare opportunities furnished by eclipses. It would seem that cirrus cloud has probably interfered with the further verification of the Einstein deflexion of light. To some this observation may appear a work of supererogation, but as an experimental problem it is very attractive, as by the photography of a field of stars a few degrees from the sun as well as that of the eclipsed sun, the agreement with theory can be more closely verified.

The British expedition near Benkulen was fortunate in weather and carried out its programme completely, but it is impossible as yet to say what results were obtained. The observers attempted to obtain spectra of the "flash" and the corona so far as possible in the infra-red and ultra-violet parts of the spectrum, where further exploration is required. One of their aims was to obtain the relative intensity of different lines of the spectrum of the chromosphere. In particular they wished to compare the intensities of two calcium lines in the extreme infra-red with *H* and *K*, as Prof. E. A. Milne had pointed out the special value of this observation in the determination of the degree of ionisation near the sun's surface. Photographs of the corona and of its spectrum, and the precise determination of the beginning and end of totality from the appearance of the "flash" lines, were also included in their programme.



Emery Walker Ltd sc.

FIG. 1.—The track of the solar eclipse of January 14, 1926.

To show what is involved in the observation of an eclipse, a more detailed account may be given of the British Expedition. In 1914 the Joint Permanent Eclipse Committee of the Royal and Royal Astronomical Societies decided that an expedition should if possible be sent to observe the eclipse of January 14 last, and it also prescribed the general lines of the research to be carried out. The Committee invited two of its number, Col. Stratton and Mr. Davidson, to undertake the task. These gentlemen had then to frame provisional estimates of the cost, so that a grant could be applied for from the Government Grant Committee of the Royal Society. When this was assured they had to decide upon the most suitable site in consultation with the Meteorological Office and the Admiralty. Their next task was to settle in detail the programme of observations, and to set about securing the best available instruments. They obtained a number of cœlostats from the Eclipse Committee, and borrowed other instruments from all sources. The Edinburgh Observatory lent a 4-inch lens of 40-ft. focus, formerly used by Dr. Copeland with a long iron trellis-work tube which could be taken to pieces and put together on the spot. The Royal Irish Academy lent a 4-inch lens of 20-ft. focus, and for a tube they adapted one made in sections and used by Greenwich observers in 1919. The Solar Physics Observatory at Cambridge lent two spectroscopes (one flint and one quartz) given to the Observatory by Col. Hills and used in several previous eclipses. In addition several prisms and speculum mirrors were collected. Other instruments, including a cinematograph, were bought by Mr. Barton, who arranged to go with the expedition as a volunteer to determine the precise instants of the commencements and end of totality. A wireless installation was kindly lent by Messrs. Burndept, Ltd., for the reception of time signals, and a recording chronometer by M. Dittisheim. The various instruments were then set up and got into approximate adjustment. Clocks were cleaned and repaired, mirrors silvered, and photographic plates and chemicals obtained. Observing huts of light wooden frames covered by waterproof canvas were constructed, the instruments and baggage were carefully packed and despatched to Liverpool for conveyance to Sumatra, the Blue Funnel Line kindly accepting this four tons as passengers luggage without extra charge.

The three observers sailed from Liverpool on November 7, and reached Benkulen, *via* Singapore and Palembang, safely with their instruments on

December 14, just a month before the eclipse. They thus had sufficient, but not too much, time to get their instruments erected and adjusted. They were joined later by Dr. Aston and Col. J. Waley Cohen, who combined a view of the eclipse with service to the party in the manipulation of their half-dozen instruments during the four minutes of totality. After the eclipse the plates must be developed, brought home and measured before the value of the results of half a year's work can be assessed. The observation of eclipses is expensive in time and money. The return on the outlay has been hitherto highly satisfactory, and we may expect that equal success will attend the latest expedition. F. W. D.

Obituary.

MR. ALFRED BELL.

MR. ALFRED BELL, who died at Ipswich on December 7, 1925, was born in the parish of St. Marylebone on June 28, 1835. During his long life of more than ninety years, he had been brought into contact with a long succession of geologists, and he was personally known to Murchison, Sedgwick, Lyell, Owen and many others. His interest in science was awakened in early years by reading illustrated popular literature, and he became a collector, with his brother Robert, a year or two older than himself, at the age of about eleven years. Robert, who also specialised in conchology, was a well-known authority on this subject. Alfred, whose interests were at first more general, obtained specimens in any way he could, partly from sailors returning from abroad, and among his personal efforts may be mentioned the collection of fossils he made from the cuttings of the Great Northern Railway, then in process of construction out of London.

Largely a self-taught geologist, Alfred Bell's education in the science began with a course of lectures he attended at a Working Men's Institute. By 1868 he had made sufficient progress to publish, in conjunction with his brother Robert, an account of the Mollusca of the Red Crag; and, somewhat later, another paper which resulted in making the acquaintance of Searles V. Wood, who was then making preparations for a supplement to his "Crag Mollusca." Robert died in 1888, and Alfred continued the work begun by his brother, with Prof. Kendall, on the newly discovered Pliocene beds of St. Erth, Cornwall. To the end of his life he worked specially at the East Anglian Crag, of which he had a remarkable knowledge. He visited all the important Pliocene deposits of Great Britain, Ireland and the Isle of Man, and he had some personal knowledge of those of Holland, Belgium and the Rhine Valley. His judgment on the specific differences of molluscan shells was regarded as particularly good, and a long list of papers on this group stands to his credit.

Alfred Bell was not one of the favourites of fortune, and he was obliged to make his living in commercial life, partly in the employment of others, but for a time as a professional collector and dealer. In the later years of his life he became the friend of Mr. F. W. Harmer, to whom he made prolonged visits, taking the greatest interest in Harmer's monograph on Pliocene Mollusca, the preparation of which was facilitated by the opportunities given by the visits for discussion and criticism. After Harmer's death, in April 1923, Bell retired to Ipswich, where he worked indefatigably until a few days before his death. His last paper, referring to the shells of the Isle of Man, was in the press when he died.

Without any special educational advantages, Bell acquired a wide knowledge, not only of his own subject, but also of others, such as archæology and history. He was of a genial temperament, possessing a considerable fund of quiet humour, and his characteristic optimism did not desert him even in his closing years, when the disabilities of old age fell heavily on him. His friends speak of him with affectionate regard.

G. MAYNARD.

REV. GEORGE HENSLOW.

THE Rev. Prof. George Henslow passed away at Bournemouth on December 30 last, in his ninety-first year. He was the younger son of Rev. John Stevens Henslow, professor of botany in the University of Cambridge, and afterwards Rector of Hitcham, in Suffolk; his mother was Harriet, a sister of the Rev. Leonard Jenyns, better known as Blomefield, a west country naturalist.

George Henslow was born at Cambridge on March 23, 1835, received his education at Sawston Parsonage, six miles to the south of Cambridge, then at the Grammar School of Bury St. Edmunds, and in 1854 became a scholar of Christ's College, Cambridge. He gained a first class in the Natural Science Tripos, and second class in divinity and mathematics. After graduating in 1858, he was ordained, and became curate of Steyning, Sussex, in 1861 receiving the appointment of headmaster of Hampton Lucy Grammar School, and four years later a similar post in London. In 1886 he became lecturer on botany to St. Bartholomew's Hospital Medical School until 1890, lecturing at other institutions also. He was a popular lecturer at the Royal Horticultural Society for many years; he had a good resonant voice, his method was attractive, his delivery clear and plain, and in the days before lantern-slides were common, at the right moment he would display a specimen or a drawing to his audience

Henslow's pen was busy upon botanical subjects, largely in a popular sense, on evolution, the fertilisation of plants, Bible plants, the origin of flowers, and the like. Some years before his death, he gave to the Linnean Society eleven volumes of reprinted papers and three volumes on Darwinian subjects. He was elected a fellow of this Society on March 17, 1864, and at the time of his death was the senior fellow but two. He was twice married, his second wife surviving, but left no family.

WE regret to announce the following deaths:

Mr. R. A. F. Murray, a pioneer of the Geological Survey of Australia and Government Geologist from 1881 until 1897, aged seventy-nine years.

Prof. W. H. Warren, Challis professor of engineering and president of the Professorial Board in the University of Sydney, and twice president of the Roya Society of New South Wales, aged seventy-three years.

News and Views.

The National Institute of Industrial Psychology announced last week that in response to its appeal for funds, issued by Earl Balfour, an anonymous gift of 10,000*l* had been received. Although the first list of donations has not yet been published, it is known that a thousand guineas have been contributed by Messrs. Debenham's and a hundred guineas by the National Union of Railwaymen. The Institute was established for promoting the study of the human factor in industry and commerce, and applying the results of such study in practice. Its investigations include the study of the best methods of work, especially the elimination of unnecessary movement, the most advantageous distribution of periods of rest and work, and the reduction of monotony. Suitable methods are devised for securing more efficient and scientific selection of workers, and better guidance of adolescents when choosing their life's work. Five years have now passed since the Institute was founded, and investigations have been carried out in twenty-six different industries. Almost invariably the resulting improvements in working conditions and methods have led to increased output accompanied by reduced fatigue, and some indication of the encouraging support and assistance given by both labour and employers is shown by the donors mentioned above. When work for private firms is undertaken, they are required to pay to the Institute a sum covering the expenses of the work, but, as with every other application of science, an enormous amount of preliminary research is essential before the results can be put into practice. The appeal for 100,000*l*. has been issued to form an endowment fund to allow of such research, and to equip a satisfactory laboratory and technical library.

Before the end of the year it is expected that radio communication will be established between all the principal dominions of the British Empire. The stations at Bodmin in Cornwall and at Bridgwater in Somerset, which are on the Marconi short-wave beam system, are practically completed, all the masts being erected and nearly all the radio apparatus is installed. The engineers are only waiting for the conclusion of the tests at Chelmsford on the transmitters and receivers before starting operation. The Bodmin station is the transmitting station with Canada and South Africa, and the Bridgwater station is the receiving station for these services. Each station has ten masts, five for each dominion. The design of the masts is identical at each station. A row of five is erected at right angles to the direction at which signals are received or emitted. The masts are 277 feet high and 650 feet apart. Each mast has a cross arm at the top measuring 90 feet. There are two parallel steel cables, separated by a distance dependent on the wave-length used and running on each side of the masts from the first to the last, a distance of about 3000 feet. Internal combustion engines are used to drive the alternators, and the various requisite voltages are obtained by motor generators. The valves are of the oil cooled type and are mounted in a separate room adjacent to the power house. Owing to the high frequencies employed, the feeders to the aerials are made of copper tubes. Both stations are connected with the London General Post Office, and the transmitting station is operated from London by "distant control." The incoming messages are automatically relayed to London. Both outgoing and incoming messages will be received at the same table in the telegraph office, thus giving true duplex working and complete central control over the traffic. Similar stations are being erected at Grimsby and Skegness for communication with Poona in India and Melbourne in Australia. At the present time Marconi's Wireless Telegraph Co., Ltd., has in hand seventeen short-wave transmitting stations.

A paper entitled "Recent Forestry Development" was read by Mr. W. L. Taylor before the Surveyors' Institution on January 11. Mr. Taylor is a member of the staff of the Forestry Commission and his paper, perhaps naturally, presents the views of that Department of the progress made in afforestation in Great Britain since the passing of the Forestry Bill in 1919 and the inauguration of the Forestry Commission. That considerable progress has been made is undeniable, but professional opinion in Great Britain cannot be termed unanimous as to the wisdom of some of the activities of the Commissioners. During the six years some 52,279 acres of conifers and 2254 acres of hardwoods have been afforested by the Commissioners In addition, as a result of grants in aid made by the Commission, a further 49,695 acres have either been planted, or the area prepared for planting, by public bodies or private individuals. Mr. Taylor states that some bad planting seasons have been experienced during the period, but is silent on the important subject of failures experienced. The remarkable afforestation work proceeding on the catchment areas of some of the big city water schemes such as Thirlmere, Derwent Valley, Vyrnwy, etc., is rightly highly commended. Up to date, the Commissioners have acquired 243,280 acres of land, of which 165,400 acres are considered to be plantable. The land appears to have been acquired at reasonable rates. One or two notable gifts of land have been made by private individuals, and the Crown Woods, Forest of Dean, New Forest, etc., have now been placed under the Commission. The scheme for the establishment of forest workers' holdings, inaugurated in 1924, should have great possibilities before it if correctly worked.

For some time past, the monthly journal *Roads and Road Construction* has been urging the necessity for organised research on road-construction, and in the January issue the question is returned to and it is pointed out, among other things, that research conducted under government auspices need in no way clash with that undertaken in private laboratories. The great problem is stated to be that of making a road capable of carrying the ever-increasing bulk of traffic and axle-weight, without having to lay down a road-crust so massive that the expense would be prohibitive. Although rural roads in Great Britain are not above suspicion, those in the United States appear to be worse; no less than 85 per cent. of them, it is stated, are nothing more than tracks and are impassable for several months in the year. Very satisfactory results have recently been obtained in North Carolina, where the sands extend for hundreds of miles along the coast, by mixing 93 per cent. of sand with 7 per cent. of bitumen, and the view is expressed that much more sand should be used for road-construction in Great Britain. To the same issue Dr. P E. Spielmann contributes an article in which he deplores the paucity of research-work on road-construction. Apart from the routine-testing of materials, the National Physical Laboratory has shelved its research work on behalf of the Ministry of Transport, and the various incorporated bodies having interests in this direction appear to be equally passive. Attention is directed to the plan of the Worshipful Company of Paviors to create a Maybury chair of highway engineering, tenable in the University of London, and the hope is expressed that research problems of basic importance will be undertaken by some government organisation appointed for the purpose.

THE report of the accountants appointed by the Board of Trade to inquire into the costs of production and financial results of the shale industry (as carried on by the undertakings associated with Scottish Oils, Ltd.) for the six months ending September 30, 1925, has recently appeared, and it makes very gloomy reading. The inquiry was held at a time when the industry was not only suffering severe economic depression, but also was harassed by acute labour troubles, the culmination of a long and critical period of commercial stress. As a result of the audit, the accountants find that there has been a net loss on the shale oil operations of the companies concerned of 77,822*l*. (for the six months in question), without allowing for plant and works depreciation; if the latter are included, the figure reaches 177,519*l*. The accounts for the same period, after allowing for income and expenditure apart from shale oil operations, and before making any provision for depreciation, show a loss of 57,776*l*. Thus the position of the industry is really quite as critical as has been evident from reports in the daily press, and it is not surprising, therefore, to find that the accountants propose that those works showing the heaviest loss per unit of output should be closed down If this policy is carried out, it will result in the cessation of operations in the Tarbrax Crude Oil Works and Mines, the Dalmeny Crude Oil Works and Ingliston Mine, the Broxburn Crude Oil Works with the Broxburn and Newliston Mines, and the Broxburn Refinery. This would mean that the remaining mines would presumably supply shale to be treated principally at the well-known Oakbank and Pumpherston refineries. There are many contributing factors to this decline of the Scottish shale industry, chief of which is undoubtedly the competition which has to be faced with regard to products from natural petroleum, and so long as the markets are swamped with such products at existing prices, so long will the oil shale industry remain at a disadvantage, both from the point of view of contemporary economics and of future development

THE Russian Society for the Study of the Urals, Siberia and the Far East is publishing, in conjunction with the All-Russian Central Executive Committee for Assistance to Northern Tribes, a new periodical, *North Asia*, devoted to the study of the northern Asiatic territories of Russia. The journal has the support of the Chief Department of Scientific Institutions (Glavnauka) and is edited by V. Vilensky-Sibernakov. The editorial staff includes a number of well-known authorities in various departments of science, economics and history. The main object of the new journal is the investigation of the economic problems of Siberia and the amelioration of the position of its native tribes. The four numbers of *North Asia* already issued contain a series of articles dealing with the natural resources of the country, its trade and industries, and a prominent place is given to sociological and ethnographical questions. There are also a number of papers on the geography, geology and history of various parts of the country. Apart from the original articles, the journal contains reviews of reports presented to the Society, bibliographical notices, and the texts of administrative and legislative Acts concerning northern Asia. All the articles are written in Russian and are not provided with summaries in a foreign language, only the title of the journal and the table of contents being translated into English.

SINCE the Belgian physicist Plateau, nearly a hundred years ago, devised a stroboscopic apparatus for the study of the vibrations of plates, many modifications of his type of apparatus have been used in practice They can be divided into two classes. In one class the moving object is only seen when it is passing through one phase of its motion. In the other, it is only illuminated when passing through one phase. In *La Nature* for December 19, a description is given of an apparatus of the latter class called the "stroborama," invented by L and A. Séguin. The great advantage of this apparatus is that it can be used in broad daylight, and so it should prove useful in studying the working of the various parts of the machines running in a factory. In a textile workshop, for example, the tension of the threads as well as the running of the reels can be examined. The electric power taken by the device is about 1 5 kilowatts. Neon tubes of great illuminating power are used. By means of a rectifier, a transformer and condensers, the tubes flash with great brilliance at periodic intervals adjusted to the period of the rotating or vibrating apparatus which is being examined. The accuracy with which the running of machines can be studied by the stroborama was demonstrated by the following experiment. Two scratches at a distance of 1 mm. apart were made on a disc. It was then rotated rapidly so that the scratches moved at a speed of 100 metres a second. When examined by the stroborama the scratches moving at this speed were plainly visible.

PROF. P. F. KENDALL, emeritus professor of geology in the University of Leeds, and Mr. T. Sheppard, of the Municipal Museums, Hull, have been elected honorary life members of the Yorkshire Conchological Society.

IT is announced in *Science* that Dr. Harris J. Ryan, professor of electrical engineering at Stanford University, California, has been awarded the Edison medal for the year 1925 by the Edison medal committee of the American Institute of Electrical Engineers "for his contributions to the science and the art of high-tension transmission of power."

THE Gold Medal of the Royal Astronomical Society has been awarded to Prof. Albert Einstein, for his relativity theory of gravitation. Prof. Einstein's name is widely known, even beyond scientific circles, through the theory of relativity originated by him in 1905 and generalised ten years later. Last year he was the recipient of the Copley Medal of the Royal Society.

THE New York correspondent of the *Times* states that Mr. Daniel Guggenheim is establishing a fund of 500,000*l.* to assist aeronautics until the freight and passenger carrying services of the United States are self-supporting. The fund is for the promotion of teaching and research in aeronautics and for the development of commercial aircraft, and the trustees are empowered to expend the whole in ten years.

THE Dominion Museum, Wellington, N.Z., has long been dangerously crowded. From the latest reports of the Director we learn that a large part of the Maori collections has been provisionally removed for exhibition to another building, and that the Government has decided to allocate the sum of 75,000*l.* towards the cost of a new building, provided that an equal sum is contributed by the public.

AT the meeting of the London Mathematical Society on Thursday, March 11, at 5 P.M., in the rooms of the Royal Astronomical Society in Burlington House, Mr. R. H. Fowler will give a lecture on "Atom-Mechanics." Members of other societies will be welcome as guests. It is hoped that Prof. A. Sommerfeld, of Munich, honorary member of the Society, will be present and speak after the lecture.

ACCORDING to a recent issue of *The Publishers' Circular*, a total of 13,202 new books and editions were issued in Great Britain during the year 1925. The number of new books was 9977. The corresponding totals for 1914 were 11,537 and 8863. Grouping the publications according to subject, the totals for the past year appear in the following order: (1) Fiction, (2) juvenile, (3) religion, (4) sociology, (5) poetry, (6) biography, (7) science, (8) technology. The order for 1914 was: (1) Fiction, (2) religion, (3) science, (4) sociology, (5) technology.

IT is stated in *Bull. No. 20 of the U.S.S.R. Society of Cultural Relations* that Prof. Elie Ivanov, well known for his numerous investigations on hybridisation by means of artificial insemination, is proceeding to French Guinea with the object of carrying out a series of experiments on the crossing of the human species with anthropoid apes at the station of the Pasteur Institute. Cross-breeding will first be attempted between the chimpanzee and orang-outang, and the baboon and gorilla. The human experiments will be conducted on representatives of some of the primitive African tribes.

THE Society for the Provision of Birth Control Clinics has issued its annual report for 1924–25. The major part of the Society's work is conducted through the Walworth Women's Welfare Centre, where 2069 new cases were dealt with during the year. From some of the cases quoted it can scarcely be doubted that such clinics under wise control serve a useful purpose. An important principle laid down by the Society is that every patient must be seen by a member of the medical staff, which is composed of medical women. We think that wherever practicable the staff should be married women. The Society depends entirely upon voluntary contributions, apart from a small nominal fee paid by patients.

A CONFERENCE was held by the Society for Experimental Biology at University College on January 7 and 8. At the morning session a general discussion was held upon respiratory pigments found in both plant and animal tissues, which was closed by Prof. J. Barcroft, who summed up the present position of the problem. In the afternoon papers were presented on the nature of protoplasmic surfaces on amœboid movement, on the hydrogen ion concentration and oxidation potential within cells, and on the occurrence of nuclear materials in certain plants devoid of differentiated nucleus. A large number of exhibits were shown during the tea interval The final session included papers on the physiological adaptation of abyssal Cephalopoda; on inheritance in *Limnæa stagnalis*; on structural growth in *Gammarus chevreuxi*, and on the relation of the effect of temperature on movement of the tail in tadpoles to its effect upon chemical reactions. At the end of the conference members of the society expressed their thanks to their hosts, particularly to Prof. D M S. Watson and Prof. J. P Hill.

COMMENTS by O. Hahn and L. Meitner on the experiments described by Dr. A. Gaschler on increasing the yield of uranium X from uranium by artificial means were referred to in NATURE of December 5, 1925, p. 827. Dr. Gaschler now writes to say that it is incorrect to state that he undertook experiments at the A.E.G. on the transmutation of uranium into uranium X with high-tension currents. He also states that accurate experiments could not be carried out at the Kaiser Wilhelm Institut fur Chemie in Berlin-Dahlem on account of lack of facilities. Most of Dr. Gaschler's work has been carried out in private laboratories.

WE have received from Messrs. Negretti and Zambra the "Easy-Setter" Thermometer Case. It consists of a clinical thermometer case of the usual type with a screw-on cap and provided with two short arms placed at right angles to the main part of the stem just below the cap. One arm is fixed to the stem, while the other is covered by a loose cylinder, so that by holding this arm between the thumb and forefinger the whole case can be made to rotate on this arm as axis. The fixed arm is milled to give purchase to the thumb and forefinger of the opposite hand in spinning the case. The principle is that of the centrifuge. The thermometer is placed in its case with the bulb downwards, the cap screwed on, and the instrument spun, when the mercury falls towards the bulb. The necessity of shaking the thermometer is thus obviated.

AN article appears in the *Fortnightly Review* for December, by J. B. C. Kershaw, on the domestic smoke problem. Data are available which show that the burning of coal in open grates contributes very largely to the haze of smoke which hangs over large towns. The use of gas coke and anthracite in closed stoves and of coal gas for heating has solved part of the domestic smoke problem, but the use of smokeless fuels in the open grate is essential before houses can be run without the production of any smoke whatever. We have also received a copy of the sixth report of the Smoke Abatement League of Great Britain, containing accounts of the annual meeting, smoke abatement exhibition, "smoke weeks," exhibits, lectures, literature, etc. The work of the League is fostered by local authorities, but the report indicates that it is hampered by lack of means.

AMONG the announcements by the Cambridge University Press of forthcoming books are "Clouds and Weather Phenomena," by C. J. P. Cave, the aim of which is the explanation of clouds, rainbows, mirages, the colours of the sky, and other atmospheric phenomena, and part 4 of "Ticks," which work is by Prof. G. H. F. Nuttall and others. The new part is by Dr. L. E. Robinson and deals with the genus Amblyomma.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A junior assistant in the physics department of the National Physical Laboratory, Teddington—The Director (February 1). Three technical assistants in the Torpedoes and Mining Department of the Admiralty—The Secretary of the Admiralty (C.E. Branch), Whitehall, S.W.1 (February 5). A junior scientific assistant in the Ignition and Electrical Department of the Royal Aircraft Establishment to assist in research in connexion with aircraft appliances—The Superintendent, Royal Aircraft Establishment, South Farnborough, Hants (February 13, quoting A. 78). The Wilson Philological lectureship for 1926–27 in the University of Bombay—The Registrar, the University, Bombay (March 10). An assistant physicist to the Linen Industry Research Association, Lambeg, Co. Antrim—The Secretary.

Our Astronomical Column.

THE NEW COSMOGONY.—An interesting article by Dr. J. H. Jeans on "The New Outlook in Cosmogony" appears in the December number of *The Nineteenth Century*. "We now get the best picture of the universe," he says, "by thinking of it as consisting of a number of sub-universes, detached from one another like islands in an ocean." Our own star-system is one such universe—"a very big island indeed, with the sun not far from its centre."

Space is not infinite, so that there are a finite number of sub-universes. As a guess we may suppose that the most remote bodies of all in our universe are at four million light-years from us. The Andromeda nebula and the star cluster N.G.C. 6822, the most remote bodies the distances of which are yet known, appear to be about one million light-years away. The history of this universe is investigated in terms of the energy changes which we deduce must occur from the fact that the stars radiate more energy than they receive. All possible sources of their energy so far suggested have proved to be altogether inadequate except that arising from the annihilation of mass. According to the theory of relativity, loss of energy must entail loss of mass, and if we suppose the mass lost to be the actual "material" mass of the atoms—the so-called "rest-mass"—then there is a sufficient store to account for stellar radiation over the periods indicated by geological and other evidence.

The life of a star on this hypothesis can be calculated, and comes out to about 200 million million years. The sun has at present lived about seven million million years, so that the greater part of its life has yet to come, although as regards magnificence it has been and will be continuously on the wane. The great length of stellar life now contemplated makes it possible that many solar systems such as ours have been formed in the past by the close approach of two stars, although, even now, "a small proportion only of the stars in the sky are likely to be surrounded by families of planets and so to form possible abodes of life." Dr. Jeans sees no prospect of a utilitarian application of the conversion of mass into energy. "So far as can at present be seen, this dream is not destined to be fulfilled."

THE BRIGHTNESS OF SATURN'S RING.—B. Fessenkoff of the Astrophysical Institution, Moscow, describes in *Astr. Nachr.*, No. 5408, some interesting comparisons of the brightness of Saturn's ring as compared with the centre of the disc; the observations were made by him and Mr. Vsechsviatsky, using a Rosenberg-surface-photometer on the 7-inch refractor of the Koutchino Observatory.

A square 5″ in the side at the centre of the disc was compared with an equal square at each ansa of the ring. The result of comparisons on five nights in June last is that the centre is brighter than the western ansa by 0·414±0·0104 magnitudes, and than the eastern ansa by 0·317±0·0057 magnitudes. The difference of 0·1 mag. between west and east was clearly shown, but can scarcely be permanent. The above differences do not directly apply to albedo, since the centre of the disc is vertically illuminated by the sun, while the illumination of the ring is very oblique. Moreover, the measures were apparently made on the outer ring A, which is well known to be considerably less bright than the outer part of ring B. Thus the albedo of the latter probably exceeds that of the disc, a result that has been obtained from earlier measures.

Research Items.

IDENTIFICATION BY RECOGNITION.—In a pamphlet called "Mistaken Identity" (London: Longmans, Green and Co., 1925, 6*d*. net), Mr. Clifford Sully discusses the psychology of recognition. A recent famous case has demonstrated only too clearly that to identify a person as a particular person is neither an easy nor a trustworthy process. Because we so frequently in ordinary life see people in their usual setting, we fail to realise how little we actually observe at the moment, as against the amount we bring to bear from memories of previous occasions. Perception and accurate observation are not the simple processes they are rashly assumed to be, nor can honesty of purpose guarantee accuracy of observation. Reference to any text-book of psychology will give the reader evidence of the complicated and personal nature of ordinary perceptions, and this can be easily demonstrated by studying some of the well-known illusions. If errors are frequently made when the mind is critical and unperturbed, how much more likely are they to be made when emotion forms the background, which would naturally be the case in connexion with police trials. Complicate the problem still further with the effect of the newspapers on witnesses, and we have a state of affairs when the probability of unbiassed judgment is exceedingly low. No experimental psychologist would accept evidence given under such conditions, and yet it forms no insignificant part of police court evidence. Nor is a feeling of certainty any proof of the truth of the judgment. The author pleads that more attention should be paid to the psychology of human testimony.

THE "ARCHAIC CULTURE" OF MEXICO.—The sensational claims made for the antiquity of the relics of human occupation discovered beneath the lava flow in Mexico Valley give an added importance to the very careful investigations which were carried out there by Mr. A. L. Kroeber in the spring of 1924. A descriptive analysis of his results have now been published in Pt. 7 of vol. 17 of the *California University Publications in American Archæology and Ethnology*. The archaic culture first began to be recognised as such in 1911 or 1912. A particular phase of it is the so-called sub-Pedregalense—a culture found beneath the lava flow or pedregal of San Angel. This is a sheet of lava of about twenty sq. km or more in Mexico Valley which issued from the peak of Ixtle, covering earlier Pliocene or Miocene andesitic flows. In parts excavated on this occasion, the cultural deposits extended to a depth of so much as 3 metres below the lava flow. Careful comparison of material from this and other archaic sites, based chiefly on the pottery, have made it possible to work out a culture sequence which falls into four periods; but the absolute age cannot yet be fixed. In the geological sense the lava flow is quite recent. Culturally the archaic period is characterised by maize agriculture; but cotton may not have been in use, as spinning appears to have been undeveloped. All the important traits of the culture are found in more developed form in the Teotihuacan culture. While it includes the general objective features of Mexican religion, it precedes the individualisation of specific deities, symbols and acts of this religion. It has no specific features characteristic of any other area, such as the Pueblo, from which indeed it is definitely marked off by the occurrence of pyramid and step structures as well as other features.

MARQUESAN MUSIC.—Mr. E. S. Craighill Handy and Miss Jane Lathrop Winne have published in *Bull.* 17, *Bernice P. Bishop Museum of Honolulu* a study of the native music of the Marquesas Islands based upon material acquired by the former when a member of the Bayard Dominick Expedition of 1920–21. In the olden days, chanting accompanied practically every activity of life among the Marquesans and formed the central feature in most rites and festivities. Twenty-five different types of chants for use on different occasions were collected on Hivaoa alone. Although solo singing was in use it was choral singing that was distinctive of their music. When a song was required for a particular occasion, the head of a family hired an adept who composed words and music. A chorus was then assembled and instructed, a special house being built for the accommodation of the singers while instruction was proceeding if the song was a tapu chant. The type of chant determined the nature of the chorus, *i.e.* whether of young girls, mixed voices, men or old men. Three types of voices in each sex were recognised, and each song had an established voice or register. For instrumental accompaniment, drums of wood and shark skin, bamboo mouth flutes and small resonant sticks were employed. The songs themselves were recreational, eulogistic or religious, while the natives themselves divided them into tapu (those with a serious purpose in view) and non-tapu (old songs which had served their purpose and were chanted for amusement, or those which were purely recreational).

IRRIGATION IN INDIA.—The Public Works Branch of the Department of Industries and Labour of the Government of India has published the Triennial Review of Irrigation in India for the period 1921–1924, from which it is to be gathered that the average area irrigated annually in British India by Government works of all classes during the triennium was 27¼ million acres, as compared with 26¾ million acres, the average of the previous triennium. In general, the results obtained have been as good as, or better than, those of the previous period, the notable exception being the United Provinces. The decrease in the area irrigated in this territory (rather more than a million acres) is attributable mainly to the favourable seasons experienced during the triennium. The total capital outlay, direct and indirect, on irrigation and navigation works, including works under construction, amounted at the end of the year 1923–24 to Rs. 89,25 lakhs. The gross revenue for the year was Rs. 10,65 lakhs, and the working expenses, Rs. 3,77 lakhs; the net return on capital was, therefore, 7·71 per cent. It is pointed out that the capital invested includes considerable expenditure upon three projects of the first magnitude, namely, the Sarda-Oudh canals, the Sutlej Valley and the Lloyd (Sukkur) Barrage projects, which are under construction and contribute nothing at present by way of revenue. The last named is the greatest irrigation scheme ever undertaken, and, when completed, it is expected to inaugurate an era of unprecedented prosperity for the Province of Sind in which it is situated. The Secretary of State for India sanctioned the project in April 1923, and the total expenditure on works, mainly of a preliminary character, including special tools and plant, during the year 1923–24 was nearly Rs. 23¼ lakhs. The Sutlej Valley project in the Punjab, sanctioned in the year 1921–22, has made good progress, and the Sarda-Oudh canals are well advanced.

SALMON AND RIVER POLLUTION.—An interesting and important report on pollution of the River Tyne Estuary, 1922–1924, by Miss Edith M. Meek, produced by the Tyne Pollution Sub-Committee, is published in the Dove Marine Laboratory Report for the year ending June 30, 1925. Pollution from various sources has resulted in a serious deterioration of the salmon industry in tidal and non-tidal waters; the ascending and descending fish both being involved, although it is specially the smolts which suffer. The smolts, about seven inches long and usually just under two years old, migrate down the river in large shoals at certain periods, and, unlike the older ascending fish, are not able to take advantage of specially favourable conditions occurring irregularly; they thus frequently enter polluted areas and are destroyed in numbers. The chief causes of pollution are sewage and effluents from works, the former causing suffocation through lack of oxygen, the latter direct poisoning Of these, however, the sewage problem is by far the more dangerous, and crude sewage is the dominant factor in the pollution of the Tyne Estuary. The report of the sub-committee is of the opinion that sewage is by far the worst enemy of the industry. Two natural counteractions are the water temperature and the presence of freshets of pure upland water resulting from rainfall, which descend in time of flood, thus forcing the polluted water out to sea and enabling the ascending fish to take advantage of the pure water. Low temperature and abundant rainfall are essential for the escape of the fish. Appendices on the bacteriology and plankton contents of the polluted areas, with statements of the numbers of fish caught, follow the report, with accounts of physiological experiments undertaken by Miss Meek, mainly on the amount of dissolved oxygen and the keeping of fish in observation tanks in the polluted water.

AN ARCTIC FISH IN BOSNIA.—In the *Novitates Musei Sarajevoensis*, No. 3 (November 1925), Dr. St. J. Bolkay records the discovery of the capelin (*Mallotus villosus*) fossilised in nodules in a clay at an altitude of 580 metres in S.E. Bosnia. The nodules resemble those containing the same fish which are often found in glacial clays in Greenland and near Ottawa in Canada. The fish exists at present in great numbers in Arctic seas and in the colder parts of the North Atlantic and Pacific Oceans. Its occurrence in clays of the Pleistocene period so far south as Bosnia is therefore a fact of great interest.

THE CLASSIFICATION OF THE FORAMINIFERA.—The attention of students of recent and fossil Foraminifera may be directed to Joseph A. Cushman's introduction to the morphology and classification of the Foraminifera (*Smithsonian Misc. Coll.*, vol. 77, No. 4, 1925). A brief account of the life-history, of the structure of the test, and of the distribution in present oceans is followed by suggestions for collecting, washing, sorting, and mounting recent and fossil examples. The terms employed in systematic descriptions are briefly commented upon and a classification into ten families follows. Under each family the constituent genera are concisely defined, and in most cases a figure is given From the point of view of the student of the test the systematic summary is admirable, but if the author had added an account of the cytoplasm and nucleus in two or three typical cases, and fuller details of the life-history, the memoir would have had a still wider appeal.

THE LIFE-HISTORY OF GORDIUS.—Dr. Jan Švábeník has issued (*Publ. Fac. Sci. Univ. Masaryk*, 58, 1925) the results of his observations on the life-history of *Gordius tolosanus*, one of the "hair worms." The primary host of this worm is the larva of some midge (Chironomidæ); Corethra and Anopheles are not infected. The first host becomes infected not by way of the mouth, but by the entry of the larvæ of the worm through the soft skin of the appendages at the hind end. The author has succeeded in infecting various carabid beetles by feeding them with midges developed from infected larvæ. The largest number of worms found in one beetle was twenty. Attempts to infect Pterostichus, Haptoterus, and Poecilus had little success, and Forficula failed to become infected. It would appear that each species of Gordius has its specific primary and secondary hosts. The development of the Gordius larva in these hosts is described and figured. The adult Gordius leaves the fat body of the beetle and issues to the exterior in the spring, the parasitic life in the two hosts having extended from July of one year to February of the next. The Gordius is free living for about four months. The author states that the gonads are endodermic in origin, and he regards the Nematomorpha as a very old group.

ALTERNATE BEARING YEARS IN TREES.—This phenomenon is very familiar in horticultural literature, so many fruit trees having a well-established habit of bearing well in alternate years; much horticultural pruning practice is directed towards restricting a habit which cannot unfortunately be given an inverse correlation with market price for the fruit. Now the same habit is reported by Mr. F. Kingdon Ward for the tree rhododendrons in his interesting account of his eighth collecting expedition in Asia, which is appearing in the *Gardener's Chronicle*. This subject is discussed by him in the issue of December 19, which contains an interesting account of a very difficult but interesting journey to the falls of the Tsangpo.

CYTOPLASM AND CHROMATIN.—Prof. Charles J. Chamberlain regards these two familiar concepts of cell-structure from the point of view of the morphologist, and in the light of his wide experience of the structure of the very large cells forming the egg cells of the Cycads, in the *Botanical Gazette* for October 1925. Prof. Chamberlain points out that these eggs are the largest in the plant kindgom, reaching a length of 6 mm., with a diameter of 2 mm., and the nuclei are exceptionally large; thus the egg nucleus of *Dioon edule* may reach a diameter of 500 μ. Prof. Chamberlain endeavours to show that in the cycad egg cytoplasm there is an unbroken series, from large vacuoles of 100 μ or more in diameter, down to the smallest spaces demanded by the theory of Bütschli and Wilson, and that the largest and smallest spaces are of the same morphological nature. He also affirms his belief that chromatin in plants is a vacuolated substance like the cytoplasm, and that, in the plants studied, there are no such structures as chromomeres upon a linin ribbon; and he predicts that theories which cannot be reconciled with a vacuolated structure of the chromosome will have to be abandoned. It is interesting to have this definite expression of morphological opinion, though the question at issue will require examination from a much wider basis than is provided by morphology.

THE ENSTATITE-AUGITE SERIES OF PYROXENES.—The importance of the pyroxenes of the enstatite-augite series, generally referred to as *augite*, has not yet been recognised in text-books, though the last decade has seen the publication of many papers on plateau-basalts in which the very widespread occurrence of that series has been conclusively established. Dr. L. L. Fermor has conveniently summarised the evidence in the *Records of the Geological Survey of India*, vol. 58, Pt. 3, 1925. He confirms Washington's conclusion that the common pyroxene of the Deccan Traps belongs to the enstatite-augite series of Wahl, the characteristic feature of these mixed pyroxenes being a small optic axial angle. It is pointed out that a research into the system $CaSiO_3$—$FeSiO_3$ is necessary before the homogeneous ferruginous varieties can be adequately explained. From the natural occurrence of monoclinic pyroxenes a provisional attempt at a classification and determinative scheme has already been made by Dr. Bror Asklund (*Sveriges Geologiska Undersökning*, Årsbok 17, Ser. C, No. 325, Stockholm, 1925). In this important paper it is shown that by taking into consideration both optic axial angles and refractive indices, the chemical composition may be approximately deduced from optical tests. Both writers direct attention to the fact that richness in $FeSiO_3$ favours the growth of a single homogeneous pyroxene, whereas both monoclinic and orthorhombic types tend to separate from magmas richer in magnesia. Further complications due to the presence of alumina have not yet been satisfactorily analysed.

EFFECTS OF PRIMARY SPHERICAL ABERRATION.—An experimental study of the effects of varying amounts of primary spherical aberration on the location and quality of optical images has been made by Miss H. G. Conrady, and her results are published in the *Journal of the Royal Photographic Society* (January, p. 9). She has worked out results by the geometric theory, by the physical theory, and by experimental work, and found that the results of these three methods do not agree, except of course in the paraxial region. "Beyond the Rayleigh limit, neither the physical nor the geometrical curves appear to agree with what actually occurs." The author finds that "without doubt" the presence of primary spherical aberration does increase the depth of definition of a lens system. As to resolving power, the curve based on the geometrical theory "obviously has no recognisable bearing on the actual facts." The experimental results agree closely with the physical theory up to about the Rayleigh limit, but beyond it there is a practical loss of resolving power. Miss Conrady gives full details of her work, and generalises her results so that they are applicable to any lens system.

THE γ-RADIATION OF THE ACTINIUM SERIES.—In the issue of the *Zeitschift fur Physik* of Nov. 28, Fraulein L Meitner, using measurements of the β-ray spectra of radioactinium and its disintegration products made by her in collaboration with Dr. O. Hahn, discusses the nature of the γ-radiation which is assumed to produce them. Both radioactinium and actinium X radiate α-particles, and possess a somewhat complicated γ-ray spectrum. Owing to their short life it is possible to employ them in very thin sheets, with the result that the lines of the β-ray spectrum are much sharper than in the case of the longer lived α-radiator radium. It is shown that the photo-effect by which the β-rays are liberated actually takes place, in both cases, not in the disintegrating atom, but in that which results from the disintegration; it follows that the γ-radiation is emitted after the α-particle has been thrown out, and represents the spectrum of the nucleus after disintegration. It is shown that the absorption within the atom, or more correctly the Rosseland photo-effect produced without actual γ-radiation, takes place, when there are several electronic levels, only in the one for which the energy of expulsion is a maximum, in the case of the L levels, for example, only in the L_1-level. The probability of absorption of the K-radiation within atoms with atomic numbers $Z=88$ and $Z=86$ is found to be of the order of ten per cent.

THE DURATION OF X-RAY PULSES.—Previous measurements of the time during which an individual X-ray pulse continues to emit energy (*Abklingungszeit*) have led to contradictory results. Dr. F. Kirchner, in the *Annalen der Physik* for November, describes an improved method for the direct measurement of the velocity of cathode rays based on that of Wiechert, and shows how it can be adapted so as to measure the *Abklingungszeit*, t_1, of X-rays. Cathode rays are emitted in large numbers from an incandescent oxide-coated cathode, are accelerated by a powerful field, passed through holes in two screens so as to form a narrow beam, and then through a rapidly alternating electric field produced by means of two hot-wire cathode valves. The beam is thus deflected in opposite directions in turn, and falling on a screen with a hole, which lets it through when it is at one of its extreme positions, falls on an anticathode producing a sudden rush of X-rays. These pass into another tube and fall on a metal cathode, from which they liberate a swarm of photo-electrons, which are accelerated by a suitable field, formed into a narrow beam by means of diaphragms, and passed through an alternating field, worked by the same valve circuit as the first, which deflects the beam to and fro. In one position the electrons can pass through a hole in a screen into the collector of an electrometer, but this will only happen when the phase relations between the field and the electron swarms are right. This depends on the length of path and the velocity of the electrons, the phenomena being also influenced by the time t_1 and by the time t_2, which is needed for the liberation of a photo-electron. The measurements show that $t_1 + t_2$ is smaller than 7×10^{-18} sec. when the K-radiation of iron is employed; t_2 is shown to be of the same order, so that the duration of an X-ray pulse must be small

THE CATHODE RAY OSCILLOGRAPH.—In the *Journal of the Franklin Institute* for December, F. R. Terroux suggests some useful improvements of the cathode-ray oscillograph which will greatly extend its usefulness. At the present time there are two distinct types of this instrument, a modified form of Braun tube and a type originally suggested by Sir Joseph Thomson and developed by D. A. Keys and A. B. Wood. Although these types have proved of value in research, there are difficulties in operating them. In the Braun type the cathode beam traces its deflexion on a fluorescent screen inside the glass tube and the luminous streak is photographed by an ordinary camera. In order to get a good image the curve must be retraced several times by the cathode beam, and this greatly limits its usefulness. In the Thomson type, the photographic plate is enclosed within the evacuated apparatus. Thus a single transit of the cathode beam will leave a distinct trace on the plate. Whenever the plate is to be inserted or withdrawn, however, the apparatus must be unsealed or evacuated anew. Mr. Terroux obviates this disadvantage as follows. A plane sheet of quartz is sealed across the end of the oscillograph tube, opposite to the cathode. A fluorescent screen is deposited on the inner side of the quartz, and a photographic plate is placed flat against the outer surface. Thus when the cathode beam traces a luminous curve on the screen, the curve would be reproduced directly on the photographic plate and the losses due to dispersion and absorption would be eliminated. There are three obvious advantages of this instrument as compared with the usual type. First, a vacuum pump is unnecessary as the tube is permanently sealed; secondly, no system of lenses is needed as the plate is placed against the quartz; and thirdly, the instrument can be used to study transient phenomena.

Prize Awards for 1925 of the Paris Academy of Sciences.

AT the annual public meeting of the Paris Academy of Sciences, held on December 14, the awards for the year 1925 were announced as follows:

Mathematics.—The Francœur Prize to Georges Valiron.

Mechanics.—The Montyon Prize (Mechanics) to René Risser for his "Essai sur la théorie des ondes par émersion." The Poncelet Prize to Denis Eydoux for the whole of his work in hydraulics.

Astronomy.—The Lalande Prize to Georges Fournier for his observations on planet surfaces and atmospheres. The Valz Prize to V Michkovitch for his works on stellar statistics. The Pierre Guzman Prize between Eugène Antoniadi (2500 francs) for his researches on the surface of the planets, Fernand Baldet (2500 francs) for his researches on the constitution of comets, and Benjamin Jekhowsky (2500 francs) for his work relating to the determination of the elements of the minor planets. The G. de Pontécoulant Prize to Paul Caubet for his work on the proper motion of the stars, the inequalities of the movement of the moon, and perturbations of the planet Ino.

Geography.—The Gay Prize to Léon Lutaud for his memoir on the tectonic and morphological study of Provence. The Tchihatchef Prize to V. A. Obroutcheff for his explorations in eastern Siberia and northern China

Navigation.—The Prix de la Marine between Pierre Marti (4000 francs) for his work on the application of sound waves to the determination of depths and positions, and André Nègre and André Vinsot (2000 francs) for their studies on the navigation of torpedoes.

Physics.—The Kastner-Boursault Prize to Eugène Darmois for his work on rotatory polarisation (natural and magnetic) and on the complex compounds of molybdic and boric acids. The Gaston Planté Prize to Joseph Bethenod for his work on the production and utilisation of high frequency alternating currents. The Hébert Prize to Édouard Roth for his work entitled "Alternateurs et moteurs synchrones." The Henri de Parville Prize to Gustave Ribaud for his work on absorption spectra and electric induction furnaces. The Hughes Prize to Jean Cabannes for his work on the molecular diffusion of light The Clément Félix Foundation (grant of 2500 francs) to Georges Déjardin for the continuation of his researches on the excitation potentials of gaseous spectra.

Chemistry.—The Montyon Prize (Unhealthy Trades) to Maurice Javillier for his work in biological chemistry. The Jecker Prize (in equal parts) between René Locquin for his work in organic chemistry and Charles Dufraisse for his researches in organic chemistry, stereochemistry, and on autoxidation. Cahours Foundation to Léonce Bert for his work in organic chemistry. The Berthelot Prize to Émile André for his work in thermochemistry, the analysis of fats, and on squalene. The Houzeau Prize to François Bourion for his work on the preparation of anhydrous chlorides and in industrial chemistry.

Mineralogy and Geology.—The Cuvier Prize to Léopold Kober for his work entitled "Bau und Entstehung der Alpen" and for the whole of his stratigraphical and tectonic work on the Eastern Alps. The Delesse Prize to François Grandjean for his researches on anisotropic liquids and on the geology of Corsica. The Raulin Prize to Georges Dubois for his researches on the Quaternary of northern France. The Joseph Labbé Prize to Marcel Solignac for his work on the geology of Tunis.

Botany.—The Montagne Prize between André de Puymaly (1000 francs) for his researches on algæ and Auguste Loubière (500 francs) for his work entitled "Recherches sur quelques mucédinées caséicoles." The Jean Thore Prize to Marcel Denis for his studies on the distribution of plants. The de Coincy Prize to Henri Chermezon for his work on the Cyperaceæ.

Anatomy and Zoology.—The Cuvier Prize to Louis Mercier for the whole of his work in zoology. The Savigny Prize to Eugène Séguy for his book on the mosquitoes of Egypt and Syria.

Medicine and Surgery.—Montyon Prizes (2500 francs) to Edmond Sergent, André Donatien, Louis Parrot, Félix Lestoquard, Edmond Plantureux, Mlle. Henriette Rougebief, of the Algerian Pasteur Institute, for their work entitled "Les piroplasmoses bovines d'Algérie", to Eugène Wollman for his memoirs on proteolysis and the Abderhalden defence ferments; and to Léon Bérard and Charles Dunet for their work entitled "Cancer thyroïdien." Honourable mentions (1500 francs) to Émile Kohn-Abrest for his work on toxicological chemistry; Georges Rosenthal for his researches on blood transfusion; and Camille Lian and André Finot for their work entitled "L'hypertension artérielle." Citations to Henri Colombiès for his experimental and clinical researches on cholesterol and its metabolism; Charles Dejean for his memoir entitled "Le canal de Cloquet, ou canal central du corps vitré"; Edmund Libert for his "Précis de pathologie générale"; Philippe Bellocq for his work entitled "L'os temporal chez l'homme adulte. Iconographie et description de l'os et de ses cavitiés." The Barbier Prize between Mlle. Fernande Coupin for work on the nervous system of vertebrates and Raymond Weissenbach for a work entitled "Les syndriomes anémiques." The Bréant Prize (arrears) to Gaston Ramon for his work on the titration of diphtheric toxin and antitoxin by means of flocculation and on anatoxines The Godard Prize to Robert Courrier for his memoir on the sexual cycle in the female of mammals. The Mège Prize to Roger Douris for his book on the analysis of the blood. The Bellion Prize to Alfred Thooris for his book "La vie par le stade." The Larrey Prize to Jules Beyne for his work on the protection of the aviator against the effects of atmospheric depression by means of oxygen apparatus.

Physiology.—The Montyon Prize to Mlle. France Gueylard for her book "De l'adaptation aux changements de salinité. Recherches biologiques et physicochimiques sur l'épinoche" The Pourat Prize to Serge Métalnikov for his work on the intracellular digestion and immortality of the Protozoa The Philipeaux Prize to Pierre Mathieu and Henri Hermann for their researches on the respiratory function by use of the tracheal air divider.

Statistics.—A Montyon Prize (1000 francs) to Maurice Fréchet for the whole of his work on the calculus of probabilities. Honourable mention (500 francs) to Maurice Halbwachs for his book entitled "Le Calcul des probabilités à la portée de tous."

History and Philosophy of Science—The Binoux Prize to Albert Maire for his bibliography of Pascal. The Henri de Parville Prize to Émile Hegh for his recent work on Termites. The Jules and Louis Jeanbernat and Barthélemy de Ferrari Doria Prize to Georges Bouligand for his work on harmonic functions.

MEDALS.—Berthelot Medals to Maurice Javillier, Charles Dufraisse, Léonce Bert, Émile André, and François Bourion.

GENERAL PRIZES.—The Grand Prize for physical sciences to Georges Mouret for the whole of his work in geology. The Lallemand Prize to Mlle. Piera Locatelli for her researches on the influence of the nervous system on regeneration. The Petit d'Ormoy Prize (Mathematical Sciences) to Jules Drach for the whole of his work. The Petit d'Ormoy Prize (Natural Sciences) to Maurice Caullery for the whole of his work in zoology and biology. The Saintour Prize to Arnaud Denjoy for his works on the calculus of primitive functions. The Lonchampt Prize between Albert Frouin and Mlle. Maylis Guillaumie (2000 francs) for their memoir entitled "La nutrition carbonée du bacille tuberculeux," and Paul Cristol (1000 francs) for his work on cancerous tissues. The Wilde Prize (in equal parts) between Raymond Jouaust for his researches on photometry and radiotelegraphy and René Mesny for his researches on radiogoniometry and short Hertzian waves. The Gustave Roux Prize to Edmond Sollaud for his researches on the embryogeny of the crustaceans The Thorlet Prize to Adolphe Richard.

SPECIAL FOUNDATIONS.—The Lannelongue Foundation between Mmes. Cusco and Rück. The Laplace Prize to D. J. L. Bichelonne. The L. E. Rivot Prize between D. J. L Bichelonne (750 francs), M. E P Pascal (750 francs), P. C. Adam (500 francs), and R. A. M. Lehuédé (500 francs).

GRANTS FOR SCIENTIFIC RESEARCH.—The following grants for research were announced:

The Tremont Foundation to Alexandre Meunier for his cartographical work on French Western Africa. The Gegner Foundation to Léon Bultingaire for his work in connexion with the preparation and publication of the catalogue of scientific publications in the libraries of Paris. The Hirn Foundation to Georges Corroy (2500 francs) for the cost of publication of a work on stratigraphy. The Becquerel Foundation to André Danjon for his astronomical works.

The Loutreuil Foundation.—I. Grants to establishments named by the founder:

(1) The National Museum of Natural History. Louis Mangin (8000 francs) for the maritime laboratory of the Museum. Désiré Bois (4000 francs) for the publication of the third volume of a guide to the collections of plants cultivated at the Museum.

(2) The National Veterinary School of Alfort. 12,000 francs to the library of this establishment for the purchase of books and more especially of periodicals.

(3) The National Veterinary School of Lyons. Joseph Basset (3000 francs) to pursue his researches on a new method of vaccination for anthrax and on the infectious diseases of the dog. Gabriel Marotel (1000 francs) for the continuation of his researches on the treatment of the parasitic diseases of animals. L. Jung (1500 francs) for pursuing his researches on the rôle of fats in the utilisation of food albumen and on the mechanism of rumination and vomiting. Armand Tapernoux (1000 francs) to continue his researches on the hydrogen ion concentration of biological liquids, particularly of milk. M. Tagand (1000 francs) to enable him to undertake, under the direction of M. Lesbre, researches on teratogenesis in various domestic mammals.

(4) The National Veterinary School of Toulouse. Jules Girard and Pierre Pons (2000 francs) for the continuation and development of their researches on the factors modifying growth (temperature, special diet, castration) P. Bru (1000 francs) for researches on pulmonary emphysema in comparative pathology. Charles Hervieux (1000 francs) for researches on the putrefaction of food.

II. Grants to establishments admitted for one year by the President. Conservatoire National des Arts et Métiers Jules Lemoine (2000 francs) for the purchase of apparatus for the physical laboratory. Gabriel Kœnigs (1500 francs) for the translation of American patents concerning various mechanical arrangements.

III. Independent grants. Jules Barthoux (4500 francs) for mineralogical researches in Algeria. General Sebert (5000 francs) for the publication of documents relating to the creation of the Office central de documentation technique et industrielle. Jacques Chevalier (1000 francs) for the purchase of apparatus for researches on experimental psychology at the new laboratory at the University of Grenoble. The Comité français de géodésie et géophysique (Section 6. Atmospheric electricity), 14,000 francs. Mme. Yves Delage (4000 francs) for the publication of a volume of "L'Année biologique." René Dubrisay (3000 francs) for the purchase of apparatus to pursue his researches in capillary chemistry. Louis Dunoyer (13,000 francs) to pursue his researches on certain problems relating to modern methods for the measurement of high vacua The Fédération française des Sociétés de Sciences naturelles (7000 francs) as a new contribution to the publication of the "Faune de France" Edmond Friedel (2500 francs) for his researches on the diffraction of the X-rays by smectic bodies. Pierre Lesne (2000 francs) for the pursuit of his researches on the coleopterological fauna of peat. Charles Marie (5000 francs) for assisting the publication of the annual tables of constants of chemistry, physics, and technology. Charles Moureu (4000 francs) for the purchase of a new type of bomb calorimeter. The Marseilles Observatory (3000 francs) for the publication of the *Journal des Observateurs* Ém. Passemard (3000 francs) for geological exploration in Syria Jean Tilho (4000 francs) for the publication of maps resulting from his explorations of Tibesti, Borkou, Erdi, and Ennedi J. Tissot (5000 francs) for assisting the publication of a work concerning the constitution of animal and plant organisms Mlle. Y. Trouard-Riolle for researches in genetics Père Lejay to complete his researches on atmospheric electricity

(The total grants from the Loutreuil Foundation given this year amount to 124,500 francs.)

The Bouchard Foundation to Henry Cardot for his work on adaptation to change of environment, heredity, Protozoa, and micro-organisms.

Annual Meeting of the Geographical Association.

"THE world about us is the greatest of all laboratories, and Nature is the greatest demonstrator." Even by the wayside, to and from school, as Prof. J. L. Myres showed, we may see processes in operation shaping the geography of the homeland and illustrating the geography of other lands. The rhythmic flow of a river, as elaborated by Dr. Vaughan Cornish, offers ample scope for training in scientific observation. Only by seeing can the eye be trained to appreciate the complex of Nature and man, the adjustment of life—social, economic and political—to its physical environment.

Sir Halford Mackinder stressed that description must be the central fact in the teaching of geography. Material must be obtained before there can be any study of causation. To describe truly, artistically and with a true sense of proportion is to reach the highest art, and such description is essential to the appreciation of a regional organisation and entity. On these grounds, Sir Halford placed geography among the arts rather than among the sciences, though, as Prof. Lyde pointed out, artistic description implies scientific method.

Regional description demands, one might almost say presupposes, a cadre or framework. Prof. P. M. Roxby dealt with the concept of natural regions in the teaching of geography, drawing his illustrations from China. The land frontiers, regarded as a zone rather than a political line, separate major regions differing from each other physically and biologically no less than culturally and economically. This difference between China and her neighbours being greater than the difference between the sub-regions of China, makes for unity in spite of its regional diversity. The major sub-regions also—the North China plain, the lower Yang-tze basin, Szechwan, south-east China and the highlands of Yunnan—reveal the same coincidence, broadly speaking, of natural and cultural divisions. Here, then, is a cadre, apparently permanent, giving definition to the geographical region with its internal complex and its external relationships.

Mr. A. G. Ogilvie outlined the extent to which such studies have been carried in South America and Africa and defined broadly the line upon which future geographical research must proceed. In both continents rapid progress is being made in topographic surveys and in the production of maps adequate for the needs of research workers. But much remains to be done. Under the auspices of the American Geographical Society much geographical work has been done in South America and more is being undertaken In Africa little geographical research has as yet been carried out, especially in British territory

Sir John Russell, in his account of "Cotton and the Nile," gave geographers two illustrations of great interest in the complexity and change of regional activities. Naturally the Anglo-Egyptian Sudan offers an important field for extensive cotton cultivation. Can the Nilotic tribes be induced to change their mode of life and grow cotton for the European market? In Egypt, on the other hand, a very distressing situation has arisen. After the expenditure of millions of pounds sterling on great schemes of irrigation, the land has begun to deteriorate quickly. For the first time in the long history of Egypt, it has been necessary to import fertilisers. Egypt is now a large buyer of nitrate of soda for the growing of crops.

Geographical economics, a term applied to the study of economics on a regional or geographic basis, forms one of the most important and most urgent fields for research. What are the fundamental causes, for example, why Malaya and British Guiana, comparable in size, position, climate and fertility of soil, should differ so widely in their total population and the export of domestic products? One has a population of 3,300,000 with export value of 78,714,225*l*. (1923), the other a population of 300,000 and export value of 3,757,647*l*. This illustration, quoted by Mr. Ormsby Gore, served as an introduction to his presidential address on "The Economic Geography of the British Empire." Under present conditions, some regions are primary producing countries, others are manufacturing. The two are complementary and both require that their economic life should be studied on a regional or geographic basis, however fully trade statistics may be studied in the abstract. To many statesmen in 1763, Guadaloupe with its slaves and sugar appeared of far greater worth than the vast forest and prairie lands of Canada because the potential geographic value was not suspected. The observations of a trained geographer capable of getting the economic survey away from a narrow view of economics on to a much wider plane are of immense value, not merely to those engaged in administration, but also for those engaged in commerce. Unfortunately, little has as yet been done in the British Empire in this direction Innumerable factors enter into an acceleration of primary production with the consequent increase of purchasing power of manufactured goods. Even in manufacturing countries, Sir Richard Gregory pointed out, inventive genius and adaptability may serve or create new needs and thus maintain or even enlarge the volume of trade between manufacturing and primary producing countries.

Altogether the papers presented at the annual meeting of the Geographical Association on January 7-9 furnished an excellent series illustrative of the theory and practice of geography.

Geodetic Observations in the United States of America.

AN official coastal survey of the United States was first authorised under President Jefferson in 1807, and since that date, with some vicissitudes, continual progress has been made in the survey of the country, both coast and inland. The Coast Survey, on account of its extended work, was renamed the Coast and Geodetic Survey, as now, in 1878. Besides the work done by this department, determinations of latitude, longitude, and azimuth have been made at various times by the U.S. Lake and Geological Surveys, the U.S. General Land Office, the U.S. and Canada Boundary Commission, the U.S. Army, and other bodies. Some of these determinations have hitherto remained unprinted, while others are scattered throughout many reports. The Coast and Geodetic Survey has therefore collected them all in one volume and made them readily and permanently available for scientific purposes.[1]

The preparation of the volume has been made by Sarah Beall, mathematician to the Survey, who acknowledges the help given by Dr. Bowie, chief of the Division of Geodesy, and all the other members of the staff of this Division. The compilation has been done in an admirably workmanlike fashion, with concise but adequate historical introductions and descriptions of the various classes of observations. There are four chapters dealing respectively with longitudes, latitudes, azimuths, and deflexions of the vertical, followed by a final chapter (occupying rather more than half the volume), giving detailed particulars of the stations. In each case the principal instruments and methods of observation and computation are described and illustrated, and the other relevant facts are summarised.

For a volume of this kind the letterpress contrives to be surprisingly interesting. The bulk of the volume, apart from the final chapter, is naturally devoted to tabular matter; the results (both as observed, and after making the various necessary adjustments) are given in order of date, the probable errors being indicated, except in the case of the deflexions of the vertical Reference to any individual station is facilitated by a comprehensive index to stations. All those who have occasion to make use of geodetic data for the United States will feel grateful to the author, and to Dr. Lester Jones, the Director of the Survey, for this very valuable collected work.

---

Contemporary Birthdays.

January 23, 1856. Brig.-Gen. Sir Henry C. L. Holden, K.C.B., F.R.S.

January 27, 1864. Prof. John Walter Gregory, F.R.S.

January 27, 1856. Prof. Edward B. Poulton, F.R.S.

Sir HENRY HOLDEN was born at Cheltenham. Educated at Ipswich School, he joined the Royal Military Academy, Woolwich, afterwards entering (1875) the Royal Artillery, and then came service in India, until 1881. The inventor of many instruments connected with electrical science and artillery problems, he became Superintendent of the Royal Gun and Carriage Factory at Woolwich; afterwards he was (1914–16) Director of Mechanical Transport at the War Office.

Prof. J. W. GREGORY, geologist and exploring traveller in many regions, was educated at Stepney Grammar School. Originally he was associated with his father in the wool trade, but in 1887, having qualified for an assistantship in the Geological Department of the British Museum, he henceforth devoted himself to scientific pursuits. He left London and Government service in 1900 to take up the post of professor of geology and mining at the University of Melbourne (combined with survey work), returning in 1904 on his election as professor of geology at the University of Glasgow. A voluminous writer in different branches of geology, Prof. Gregory has studied in particular the features of the Alps, the Mediterranean basin, Africa, the West Indies, and Australia. Among his publications are "The Origin of the Great Rift Valley in East Africa," "The Origin of Fjords," "The Evolution of the River Systems in Chinese Tibet." Prof. Gregory was president of the Section of Geology, British Association, 1907, and of the Section of Geography, 1919.

Prof. E. B. POULTON was born at Reading, the son of an architect resident there. He was educated in the first instance at a private school, afterwards entering and graduating at Jesus College, Oxford. For many years (and still) Hope professor of zoology in the University of Oxford, early a Burdett-Coutts university scholar, an ex-president of the Oxford Society, lecturer in natural science at Jesus College, sometime tutor at Keble, formerly a member of the Oxford Hebdomadal Council—in short, all Prof. Poulton's traditions and implications savour of Oxford. President of the Linnean Society, 1912–16, he was awarded (1922) the Linnean gold medal, in token of the Society's appreciation of services to zoological science. Sir A. Smith Woodward remarked at the time that Prof. Poulton had begun by traversing a wide field, from bone-caves and Pleistocene geology to the structure of the tongues of marsupials—histological work which culminated in the interesting discovery of true teeth in the embryo Ornithorhynchus. Prof. Poulton's inclinations, however, were always towards entomology, and for many years he has been regarded as the chief exponent of the theory of protective resemblance and mimicry in insects. His keepership of the Hope collection at Oxford has resulted in the creation of a museum of entomological specimens illustrative of variation, geographical distribution, and mimicry bearing on the theory of evolution. He has also carried out experimental breeding work on variable protective resemblance, demonstrating the dependence of the coloration of certain larvæ and pupæ on the particular circumstances of their environment. His work was rewarded in 1914 by the Royal Society's Darwin medal.

Early Science at Oxford.

January 25, 1683–4. A letter from Mr. Aston gave an account, of ye specific difference between ye Christalls of Sea-salts and common salt, or Inland salt, which consists in this: The angles of ye Chrystalls of common salt are entire (as likewise are those of *Sal Gemmæ* and ye lixiviated marine salts of Dr. Grew) but ye angles of true sea-salt are cut off, into triangular planes, at least in one of ye sides. Dr. Plot shewed us some Chrystalls of sea-salt, in which we observed ye triangular plane mentioned in Mr. Aston's letter. The severity of ye frost led us then to discourse of cold, particularly of making holes in ye Ice with salt, which eats through ye ice, which means ye common-people make use of, in opening their frozen pumps.

January 26, 1685–6. A paper of Dr. Papin's explaining his new way of raising water was presented and read.

Mr. LLoyd communicated a paper containing an account of some plants, which grow in North Wales, and are omitted in Mr. Ray's catalogue.

Dr. Plot presented an old almanack sent him out of Somersetshire.

January 27, 1684–5. An answer to Dr. Middleton, provost of Kings Colledge in Aberdene, was drawn up, concerning the establishing a Correspondence between us of this Society, and ye Gentlemen of Aberdene.

The Society, being acquainted, that, in Hullington-fields, in Wiltshire, there is an odd sort of light barren earth; and that severall curious plants grow thereabout; gave order, that Dr. Plot, at his return to Oxford, be desired, to write to Mr. Cole of Bristoll, (to whom this land belongs,) and make use of his interest with that gentleman, for ye procuring an account of these matters.

Sir William Petty having thought it worth his while, to enquire into ye proportion of ye materials, used in making severall sorts of Mortar, the following report was drawn up: The Mortar used by our Plaisterers is generally of two sorts, course or ffine: 1. *Course* mortar is made of Lime, sand, and hair. the Lime used here at Oxford is of 2 sorts, viz Chalk-lime, made of a Chalk-stone dug at Nettlebed, and other places, and burnt: or 2dly Hard stone lime, which is made of hard rag stone, burnt; this last sort of lime is much stronger, and will go 2 yards square in five, farther, (for it takes up far greater quantity of sand, and water,) than ye former, which is the finer of ye two, and ye more beautifull, and glorious, to the eye.

One bushell of chalk lime, one bushell of sand, and one peck of hair, mixt all together with water, will make *course* Mortar: but if you use hard stone lime, then one bushell of Lime will require a bushell and ½, or 2 bushells, of sand, and a bushell of hair. In ye making of *fine* mortar mix one bushell of chalk lime with ½ a peck of hair, or a bushell of hard stone lime with a peck of hair, and as much water as is necessary. Course mortar is used next to ye lathing, or ye stone, or brick-wall; ffine mortar is drawn on ye other, makes it white, and beautifull.

Clay mortar, or Loam mortar, is made with clay, and as much chopt straw, as ye clay will take in by ye help of water.

Whiting is made by dissolving Spanish white either in size, or in water, that with size is not easily rub'd off.

That substance, which is commonly sold at London for about 1d. p pound for Spanish white, is supposed to be made of chalk ground, and made up into Balls with water.

Societies and Academies.

LONDON.

Royal Society, January 14.—Leonard Hill and Y. **Azuma**: Effects of ultra-violet radiation upon involuntary muscle and the supposed physiological interference of visible rays. No physiological interference is produced by dark heat or visible rays with the exciting action of ultra-violet on involuntary muscle. The action of ultra-violet rays antagonises that of adrenalin on involuntary muscle, but not that of emetin. The presence of calcium in the nutritive fluid is necessary for the increase of tone produced by ultra-violet rays.—I. de B. **Daly**: A closed-circuit heart-lung preparation; effect of alterations in the peripheral resistance and in the capacity of the circulation. A diminution in capacity of the systemic circulation produces the same effects qualitatively and quantitatively as an increase in the volume of circulating blood, namely, a rise in pressure in both auricles, the aorta and the pulmonary artery, and an increase in the cardiac output. An increase in peripheral resistance has an opposite effect. "Resistance," "capacity" and blood distribution effects are interdependent, their relative effects being determined by the physical constants of the circulation.—C. H. **Best**: On the effect of insulin on the dextrose consumption of perfused skeletal muscle. Insulin greatly accelerates the rate of sugar disappearance from defibrinated blood used to perfuse the isolated limbs of the cat. The action is attributable to its effect on the metabolism of the skeletal muscles.—T. S. P. **Strangeways** and Honor B. **Fell**: Experimental studies on the differentiation of embryonic tissues growing *in vivo* and *in vitro*. (i.) The development of the undifferentiated limb-bud (*a*) when subcutaneously grafted into the post-embryonic chick, and (*b*) when cultivated *in vitro*.—C. N. **Long**: Muscular exercise, lactic acid, and the supply and utilisation of oxygen. Pt. xiv. The relation in man between the oxygen intake during exercise and the lactic acid content of the muscles. In men, as well as in the isolated muscle, the rate of removal of lactic acid, as measured by the oxygen intake, is proportional to the square of the lactic acid concentration in the fluids which are in contact with the muscle fibres. Lactic acid apparently acts as a "governor of oxidation" in the recovery process of muscle.—K. F. **Hetzel** and C. N. **Long**: The metabolism of the diabetic individual during and after muscular exercise. Muscular exercise in the diabetic individual appears to be accompanied by the same metabolic changes as in the normal. Exercise increases the combustion of carbohydrate. For short periods of exercise, with insulin administered during the last 17 hours, the respiratory quotient of the excess metabolism is unity, exactly as in normal men: for exercise of moderate duration its value is intermediate, while for exercise of long duration it tends to fall towards that of the previous resting metabolism. In this respect the diabetic individual with recent insulin, on a diet poor in carbohydrate, behaves in a manner exactly similar to a normal man on a diet consisting mainly of fat, though the phenomena are more exaggerated. In a diabetic individual without insulin, the respiratory quotient of the excess metabolism is always low. It may be supposed that a muscle, for its oxidative processes in recovery from exertion, uses carbohydrate only; that in the presence of insulin there are stores of carbohydrate in a form readily available for use by the muscle, and that a short interval of exercise does not sufficiently deplete these stores to render an immediate restoration necessary from other substances in the body. In the absence of insulin, these ready stores of carbohydrate have run low. Prolonged muscular exertion, a diet poor in carbohydrate, and the absence of insulin, all produce the same effect, namely, a lowering of the respiratory quotient of the excess metabolism due to exercise. All these factors might be expected to deplete the stores of carbohydrate readily available.—W. G. **Millar**: The diffraction method of measuring the diameter of erythrocytes.

SYDNEY.

Royal Society of New South Wales, December 2.—A. R. **Penfold** and R. **Grant**: The germicidal values of some Australian essential oils and their pure constituents, together with those for some essential oils. The published value for terpineol (Rideal-Walker test) is 16. Some other results are: *Atherosperma moschata* (crude oil), 18; formic acid, 5; butaldehyde, 12 (5); butyric acid (normal), 1 (8); butyl butyrate, 13 (17). Figures in brackets are due to either increased or decreased dispersion brought about by solution in alcohol instead of 7·5 per cent. rosin soap solution.—A. R. **Penfold**: The essential oil of *Bæckea Gunniana* var. *latifolia* (F. v. M.). This Myrtaceous shrub is widely distributed throughout the mountains of New South Wales. The yield of oil from the leaves amounted to 0·33 to 0·74 per cent, and its melting-point was 43° to 47° C. It is the only Australian essential oil which has yet been recorded that becomes a solid at ordinary temperatures. It contains more than 60 per cent. eudesmol, eudesmene, b-pinene, small quantities of unidentified phenolic bodies, and valeric acid ester and a stearoptene.—F. A. **Coombs**, W. **McGlynn**, and M. B. **Welch**: The black cypress pine (*Callitris calcarata*, R. Br.) tannins and their distribution in the bark. This tree occurs over a large area of Australia, and possesses a valuable tan-bark containing up to 36 per cent. tannin. Difficulty has been experienced in obtaining a satisfactory commercial extraction, due to regularly recurring bands of cork cells, impervious to water, at close intervals now observed. By grinding the bark to a powder, this difficulty can be overcome. Starch, which is a most important agent in the destruction of tannin when extraction is carried out at high temperatures, was observed in those cells of the inner living bark in which tannin is situated. The bark of this tree is available in large quantities, and is very suitable for the production of a tanning extract. It resembles in many respects the North American hemlock bark, but its tannin content is at least double.—C. A. **Sussmilch**: On the occurrence of waterworn pebbles of coal in the Upper Coal Measures at Red Head, N.S.W. Analysis of one of the pebbles, together with its physical character, indicates a probable derivation from the Greta Coal Seam in the Lower Coal Measures. This indicates that the Lower Coal Measures must have been undergoing denudation during the time that the Upper Coal Measures were being laid down, and therefore, that some crustal movements must have taken place between the deposition of the two coal measures.—Ida A. **Brown**: Some tertiary formations on the south coast of N.S. Wales, with special reference to the age and origin of the so-called "silica" rocks. The flinty quartzites discussed occur on the south coast of New South Wales and in the Ulladulla District, and are quarried as "silica" for use in the manufacture of bricks for lining steel-furnaces. Hitherto they have been regarded as the result of the metamorphism of Upper Marine (Permo-Carboniferous) sandstones by volcanic dykes, but it is considered that they are derived from very pure siliceous sediments of Tertiary age, which have been hardened and compacted by subsequent flows of olivine basalt. Well-preserved fragments of the stems and roots of a dicotyledonous angiosperm were found in the quartzite.

VIENNA.

Academy of Sciences, November 5.—**K. Chudoba**: The dispersion of plagioclase. The gray-position-method has already been applied to determine the situation of the optical axes for different wave-lengths in orthoclase. With albite the dispersion of the B-axis is about three times as great as that of the A-axis. Measurements were made with monochromatic light of six different wave-lengths, and the situation of the axes controlled by the right angle method.—**B. P. Wiesner**: On the function of the germinal gland before puberty; experiments on rats. (I.) Castration of new-born males. The development of sexual characters at puberty is dependent on the endocrine function of the reproductive system. Castration was performed twelve hours after birth, and the after-growth of castrated, one-side castrated, and entire animals compared at various ages. Development continues for a few days only after complete castration; normal and half-castrated animals develop alike. (II.) Spaying of new-born females. In contrast to the males, the normal and spayed females develop alike up to puberty, and only the onset of the œstrus cycle and its periodic recurrence proves the secretory function of the ovary. There is no œstrus in spayed animals, but the earlier stages of the development of sexual characters are independent of the ovary. Details of these researches will appear in *Pflüger's Archiv f. d. ges. Physiologie*.—**P. Weiss**: The morphological impotence of regeneration tissue. The formation of extremities from tail material from Triton. Transplantation was made from the middle of the tail into the body wall near the fore-limb. Various effects took place—healing over, a small tail, warty lumps or a differentiated limb. The regeneration tissue when young seemed to be undifferentiated, and its subsequent growth was determined by the position into which it was transplanted (morphological impotence). Older material, to a certain degree determined as tail, formed tail after transplanting.—**K. Grobben**: Attempt at an explanation of the alternation of layers in pearls.—**H. P. Cornelius** and **M. Cornelius-Furlani**: Report on geological inquiries on the Insubrisch line in the lower Val Tellina. Two quite different zones occur; in the north, highly crystallised biotite-gneiss with intrusions, and in the south, uniform quartz-phyllite.

November 20.—**G. Weissenberger, S. Baumgarten** and **R. Henke**: Absorption by charcoal from viscous media.—**J. Zellner** and others: Contributions to the comparative chemistry of plants, XI. The chemistry of barks. In the barks of Cornus, Tilia and Carpinus, substances have been found such as alnulin, coryliresinol and platanol acid.—**J. Braunhauser**: The chemistry of heterotrophic phanerogams. Mistletoe berries have been analysed.—**A. Huber**: Newton's method of approximation.—**Skrabal** and **A. Zahorka**: The hydrolysis of acetic acid ester by acids.—**J. Pia**: The structure of the Alpine middle-trias deduced from the diplopores.—**H. Handel-Mazzetti**: New Chinese plants (36). Includes species of Aconitum and Corydalis.

November 26.—**K. Umrath**: On the conduction of irritability in Mimosa. In *M. Spegazzinii* as in *M. pudica* there are several stimulus conducting systems. Three velocities of conduction were found in the leaf and two in the stem.—**O. Pesta**: Problems of the hydrobiology in the mountains of the Eastern Alps. Chemical analyses have been made of the waters of mountain lakes.

December 3.—**H. Hahn**: On a theorem of existence in the calculus of variations, and on the method of arithmetical means in the theory of generalised Fourier integrals.—**H. Handel-Mazzetti**: New Chinese plants (37). Three species of Pedicularis are described.

December 10.—**F. Becke** and **J. E. Hibsch**: On nephelines with zonal structure.

Official Publications Received.

SATURDAY, JANUARY 23.

British Mycological Society (at University College), at 11 A.M.—B. Barnes: Preliminary Observations on the Physiology of *Lachnea*.—A. Chaston Chapman: A Plea for a National Institute of Industrial Micro-Biology.—Kodak Ltd.: The Eastman Colorimeter.—J. Ramsbottom: Fragmenta Mycologica V.—G. Tandy: Cytology of *Pyronema domesticum*, Sacc.—W. M. Ware: *Pseudoperonospora Humuli*, Miyabe and Tak, and its Mycelial Invasion of the Host Plant.

Electrical Association for Women (at Æolian Hall), at 3.—Demonstration of the Application of Electricity in the Production of Music for the Home.—H. V. Spanner: The Place of Music in the Home (Lecture).

Royal Institution of Great Britain, at 3.—H. Balfour: The Evolution of Currency and Coinage.

Physiological Society (at National Institute for Medical Research).

MONDAY, JANUARY 25.

Royal Irish Academy, at 4.15.

Royal Society of Edinburgh, at 4.30.—Prof. T. J. Jehu and R. M. Craig: Geology of the Outer Hebrides. Part 2, North Uist and Benbecula.—Dr. P. M. Finlay: The Old Red Sandstone of Shetland. Part 1, Eastern Area. With Notes on the Fossil Fishes of the Old Red Sandstone of the Shetland Islands. By Sir A. Smith Woodward and E. I. White.—Prof. J. K. Charlesworth: (*a*) The Great Re-Advance Kame-Moraines of the South of Scotland, and some Later Stages of Retreats; (*b*) The Glacial Geology of the Southern Uplands of Scotland, West of Annandale and Upper Clydesdale.—Dr. A. E. M. Geddes: The Distribution of Electric Force in High Voltage Discharges.

Victoria Institute (at Central Buildings, Westminster), at 4.30.—Lt.-Commdr. V. L. Trumper: Modern Science in the Book of Job.

Institute of Actuaries, at 5.—C. F. Warren: An Investigation into the Mortality experienced by Pensioners of the Staffs of Banks and Insurance Companies, with a Note on the Mortality experienced by Deferred Annuitants.

Royal College of Surgeons of England, at 5.—Sir Arthur Keith: Fossil Remains of Ape and Man (4). The Taungs Anthropoid: its Zoological and Geological Position.

Royal Society of Medicine, at 5.—Lord Dawson of Penn and others: Discussion on Hyperpiesia.

Institution of Electrical Engineers (Informal Meeting), at 7.—Discussion: Impressions on my Visit to America, mainly about Switchgear.

Institution of Electrical Engineers (North-Eastern Centre) (at Armstrong College, Newcastle-upon-Tyne), at 7.—Capt. P. P. Eckersley: The Past, Present, and Future of Wireless Telephony.

Royal Society of Arts, at 8.—H. P. Shapland: The Decoration of Furniture (Cantor Lectures) (2).

Royal Society of Medicine (Odontology Section), at 8.—A. W. Wellings: Some Points in the Anatomy of the Capillaries of the Tooth Pulp.—W. Harrison and E. W. Lowe: Notes of a Complicated Removal of a Third Lower Molar—Fatal Sequel.

Royal Geographical Society (at Æolian Hall), at 8.30.—H. J. L. Beadnell: Recent Travels in Central Sinai.

Medical Society of London, at 8.30.—R. C. Elmslie, W. R. Bristow, and others: Discussion on Manipulative Treatment in Medicine and Surgery.

TUESDAY, JANUARY 26.

Royal Dublin Society (at Ball's Bridge, Dublin), at 4.15.—Prof. F. E. Hackett and others: Discussion on Recent Theories of Stellar Evolution.

Royal Institution of Great Britain, at 5.15.—Prof. J. A. Crowther: X-rays and Living Matter (2).

Institution of Civil Engineers, at 6.—A. S. Angwin and T. Walmsley: Rugby Radio Station.

Institute of Marine Engineers, at 6.30.—F. A. Best: The Flettner Rudder.

Institution of Automobile Engineers (Informal Meeting) (at 83 Pall Mall), at 7.—Discussion on Tire Pumps and Jacks.

Institution of Electrical Engineers (North Midland Centre) (at Hotel Metropole, Leeds), at 7.—L. H. A. Carr: The Use of Induction Regulators in Feeder Circuits.

Royal Photographic Society of Great Britain, at 7.—A. S. Newman: Three Fallacies in Kinematography.

Institution of Engineers and Shipbuilders in Scotland (at 39 Elmbank Crescent, Glasgow), at 7.30.—G. J. Lugt: The Werkspoor Diesel Engine.

Royal Anthropological Institute, at 8.30.—Anniversary Meeting.

Royal Society of Medicine (Medicine and Comparative Medicine Sections), at 8.30.—Sir Humphry Rolleston (Medicine), Prof. Wooldridge (Comparative Medicine), and others: Discussion on Hodgkin's Disease in Man and Animals.

Institution of Electrical Engineers (Western Centre) (South Wales Institute of Engineers, Cardiff).—A. P. Trotter: Illumination and Light (Faraday Lecture)

WEDNESDAY, JANUARY 27.

Leeds Philosophical Society, at 5.

Royal Society of Medicine (Comparative Medicine Section), at 5.—Prof. R. H. A. Plimmer: The Relation of Quantity of Vitamin B to Quantity of Food.—Prof. J. C. Drummond: New Facts concerning the Fat-soluble Vitamins.

Royal College of Surgeons, at 5.—Sir Arthur Keith: Fossil Remains of Ape and Man (5) Fossil Anthropoids of Europe and of Asia.

Newcomen Society for the Study of the History of Engineering and Technology (at 17 Fleet Street), at 5.30.—D. Brownlie: John George Bodmer, his Life and Work, particularly in the Evolution of Mechanical Stoking.

Radio Society of Great Britain (at Institution of Electrical Engineers), at 6.30.

Institution of Electrical Engineers (South Midland Centre) (at Birmingham University), at 7.—C. E. Webb: The Power Losses in Magnetic Sheet Material at High Flux Densities.

Institute of Metals (Birmingham Local Section) (jointly with Birmingham Metallurgical Society) (at Temperance Hall, Temple Street, Birmingham), at 7.—W. R. Barclay. Metallurgy of Nickel with Special Reference to Work in Canada

Institution of Automobile Engineers (North of England Centre) (at 244 Deansgate, Manchester), at 7.15.—J. D. Parkes: Logic applied to Failures.

Glasgow University Alchemists' Club (jointly with Andersonian Chemical Society), at 7.30.

Institute of Chemistry (Edinburgh and East of Scotland Section) and Society of Chemical Industry (Edinburgh and East of Scotland Section) (at 36 York Place, Edinburgh), at 7.30.—Dr. A. E. Dunstan: Recent Developments in the Refining of Petroleum.

Royal Society of Arts, at 8.—Prof. J. McLean Thompson: Some General Problems of the Transport by Sea and Conservation in Store of Ripe Fruit (Aldred Lecture).

Eugenics Education Society (at Royal Society), at 8.30.—Prof. F. G. Parsons: The Earlier Inhabitants of London.

British Psychological Society (Medical Section) (at Royal Society of Medicine), at 8.30.—Dr. M. Culpin: Investigations into the Predisposition to Breakdown.

THURSDAY, JANUARY 28.

Royal Society, at 4.30.—Prof. A. C. Seward: The Cretaceous Plant-Bearing Rocks of Western Greenland.—Dr. W. L. Balls and H. A. Hancock: Measurements of the Reversing Spiral in Cotton Hairs.—R. H. Burne: A Contribution to the Anatomy of the Ductless Glands and Lymphatic System of the Angler Fish (*Lophius Piscatorius*).—I. Gordon: The Development of the Calcareous Test of *Echinus miliaris*.—*To be read in title only*:—F. G. Gregory and L. Batten: A Critical Statistical Study of Experimental Data on the Effect of Minute Electric Currents on the Growth Rate of the Coleoptile of Barley.—H. M. Fox: Chlorocruorin: a Pigment allied to Hæmoglobin.

Royal Institution of Great Britain, at 5.15.—Prof. C. J. Patten: The Breeding Factor in Birds.

Institute of Chemistry Students' Association (London) (at Institute of Chemistry), at 8.—G. Lemoneus: The Transference of Chemical Processes to the Large Scale (Address).

FRIDAY, JANUARY 29.

Royal College of Surgeons of England, at 5.—Sir Arthur Keith: Fossil Remains of Ape and Man (6). The Kivu Gorilla and its Bearing on the Problems of Human Evolution.

Institution of Structural Engineers (Yorkshire Branch) (at Great Northern Hotel, Leeds), at 6.30.—D. Davidson: A New System of Reinforced Concrete Construction and its Application to Foundations on Silt and Running Sand.

Junior Institution of Engineers, at 7.30.—A. N. Moon: Comfort in Railway Travel from the Point of View of the Engineer.

Royal Institution of Great Britain, at 9.—Sir William B. Hardy: On Films.

Manchester Literary and Philosophical Society.

SATURDAY, JANUARY 30.

Royal Institution of Great Britain, at 3.—H. Balfour: The British Coracle, or Skin-covered Boat, and its Affinities.

North of England Institute of Mining and Mechanical Engineers (Associates' and Students' Section) (at Neville Hall, Newcastle-upon-Tyne), at 5.—P. F. Hope: The Sinking of Monkton Shaft.—J. T. Pringle: Housing of Workmen (Discussion).

Institute of Metals (North-East Coast Local Section) (jointly with Institution of British Foundryman) (at Neville Hall, Newcastle-upon-Tyne), at 6.15.

PUBLIC LECTURES.

SATURDAY, JANUARY 23.

Horniman Museum (Forest Hill), at 3.30.—Miss M. A. Murray: Europe's Debt to the Ancient Egyptians.

MONDAY, JANUARY 25.

University of Leeds, at 5.15.—Prof. G. Watson: Approximations.

King's College, at 5.30.—Dr. F. A. P. Aveling: The Human Will: Medieval Views.

University College, at 6.—H. D. J. White: Psychology of Art: Beauty and the Unconscious.

TUESDAY, JANUARY 26.

University College, at 5.30.—Miss M. A. Murray: Egyptian Architecture.

SATURDAY, JANUARY 30.

Horniman Museum (Forest Hill), at 3.30.—H. Harcourt: Glimpses of Indian Places and Peoples.

CONFERENCE.

WEDNESDAY, JANUARY 27.

Rothamsted Experimental Station, Harpenden, at 11.30 A.M.—The Growing of Lucerne. Chairman: Lord Clinton. Speakers: Sir E. J. Russell: Spread of Lucerne Growing.—Prof. R. G. Stapledon: Lucerne in High and Wet Districts.—J. Mackintosh: Lucerne for the Dairy Farmer.—A. Cunningham: Scottish Experiments with Lucerne.—H. G. Thornton: Inoculation of Lucerne.

SATURDAY, JANUARY 30, 1926.

Electric Supply in Great Britain.

UNTIL the details of the Government electric supply scheme for Great Britain outlined by Mr. Baldwin on January 15 are published, it is only possible to discuss the scheme in a general way. It may be useful, however, to give a brief survey of the conditions affecting electric supply in Britain. The proposals are of national interest, affecting directly not only the electrical industry but also the many industries for which electric power is a necessity. They also affect every one who uses or in the future may use electricity for domestic purposes.

Situated all over the country are 584 public supply stations. A few of these are large and highly efficient, but several are getting antiquated. They are operated by private companies, municipalities and "joint authorities" in accordance with the Electric Lighting Act of 1919. Some of these are authorised to supply electricity in bulk, and these will retain their powers. After the electricity is generated it is transmitted to distributing stations, where the business of the engineers is to make arrangements for supplying consumers with electric power and light. The scheme is to eliminate gradually the inefficient generating stations and convert them into distributing stations. They will purchase their electricity in bulk from a central board, which will own a huge distributing network of mains. This board will purchase its electricity from a selected number of existing generating stations, and after paying the small expenses of management and the interest and sinking fund on its network, will apply any surplus to the cheapening of the cost to the consumer.

The scheme is not exactly novel, as a somewhat similar one was suggested for Great Britain and discussed in the electrical press last year. It seems, however, to have been studied in detail by the Electricity Commissioners, who approve of it. It will be useful, therefore, to consider the beginnings of electric supply in Great Britain and to discuss some of the problems that will want careful consideration. There will be no Government subsidy, but the interest on the capital required to purchase the transmitting mains and to pay for the cost of their erection will be guaranteed by the Government under the Trade Facilities Act.

The evolution of the method of supplying electricity over considerable distances was started by Ferranti about forty years ago. He designed a station at Deptford for generating electrical energy at 10,000 volts and transmitting it to substations in London, where it was transformed down to lower pressures and distributed to consumers. The site was chosen in a place where there was abundant water for condensing purposes and where coal was cheap owing to the low costs of transport. The late Lord Crawford was very enthusiastic over the scheme and was one of its strongest supporters. It needed great courage and great faith in science in those days to undertake such an experiment. It is interesting to remember that it is this station which supplies the power required by the Southern Railway to work its electrified sections. Ferranti is universally recognised as the pioneer of modern electric supply. The Government legislation of this period made electric supply very difficult. London was divided up into small areas, each of which was to be supplied by two companies, one using direct current and the other alternating current, the idea being that the competition between the two would tend to cheapen the supply. Under such conditions, it is surprising that any company survived, seeing that security of tenure was only given for a limited number of years.

In 1919, only seven years ago, the Government again introduced legislation affecting the industry. The country was divided up for electrical purposes into a number of districts, each of which was practically autonomous, and powers were given for the erection and working of large generating stations by joint authorities. The new scheme considers that England is not too large to be considered as a single unit, the generating, transmitting and distributing parts of the industry being kept quite distinct. It has been very cleverly arranged that the new scheme will gradually come into operation with the minimum disturbance of existing arrangements, and yet, in ten or fifteen years' time, the great bulk of the public who use electricity will be supplied at very much cheaper rates.

At first sight, we picture this national system of transmitting lines as extending from Land's End to Thurso, and from Glasgow to Newcastle, Birmingham and London. To diminish the cost of transmission, if not 220,000 at least 110,000 volts must be used. A little consideration, however, will show that the cost of the mains required in this case would be altogether prohibitive. Still we consider that in ten years' time the length of the lines necessary to link up all the centres of supply will be at least 2000 miles and the cost of overhead mains would be at least 6,000,000*l*. It has also to be remembered that there will be a heavy additional expenditure at the distributing end of the mains due to the rotary converters or mercury arc rectifiers which would probably be used to lower the pressures and convert the alternating current supplied into direct current.

It will be seen that a national transmission network can only be erected at a very great capital cost, and interest, depreciation and maintenance will be very heavy items. But we think that, provided the scheme is not rushed unduly but allowed to develop gradually, it is a good and sound commercial proposition. In any case, owing to the Government guarantee, we think that the requisite capital will easily be obtained. It has been suggested that it may be possible in the future to transmit electric power through the ether without transmission cables at all. With our present knowledge of science, however, this suggestion, like the corresponding one of obtaining energy from the atom, need not be seriously considered for many years to come.

In our opinion, Mr. Baldwin perhaps laid unnecessary stress on the standardisation of the frequency. Most electricians agree that 50 should be the standard frequency and that every new station should have this frequency, but there is no urgent necessity for scrapping the existing generators and apparatus which work at other frequencies. It is a very simple operation to link two networks together by suitable synchronous motor-generator sets so that power can be transformed from one to the other quite easily.

This national network will provide a large number of problems for mathematical engineers. In Great Britain, hitherto, it has been permissible to assume that the capacity and inductance of the mains can be supposed to be concentrated at particular points of the mains. In the future, this assumption will seldom be admissible as the networks will be large and hyperbolic sines and cosines will have to be used in making the requisite calculations. Again it will not be sufficient to assume that the most economical site is the centre of gravity of the load. Lengthy calculations will have to be made, and the problem of finding which site is the best will have to be investigated much more minutely in the future than in the past. Competent mathematicians should be in great demand.

Unfortunately, there is not yet a 1,000,000 volt testing transformer at the National Physical Laboratory for testing the high voltage insulators which will have to be used. Progress in this direction should be accelerated. The physics of the brush discharges, generally called the corona, which appear sometimes on high tension mains, have been thoroughly investigated in the United States.

Mr. Chattock, in his presidential address to the Institution of Electrical Engineers, pointed out that it would be very difficult to supply rural districts at a reasonable rate by tapping the high tension mains directly, as this is always a costly process. The connexions would have to be made at well-defined centres, from which light overhead wires carrying currents at low pressures would radiate in all directions. The present high price of wiring cottages in rural England for the electric light is due to the very stringent regulations under which wiring contractors have to work. On the Continent, the cost is only about a third or a quarter of what it is in England. There is a considerable margin, therefore, for reducing the price of wiring by lowering the pressure of supply sufficiently so that much less stringent regulations could be used.

We hope that something will be said in the promised Bill about electrifying the railways and equipping every coal mine in the country with complete electrical plant for getting the coal and for pumping and ventilating. Expenditure of this kind is immediately remunerative, and the Government guarantee would help to foster what the Americans call " public utility " services.

One great advantage of interlinking supply stations is that the supply of reserve plant will be largely reduced. The Electricity Commissioners have stated that 68 per cent. of the generating plant in Great Britain is normally idle. We were glad that the Prime Minister in his speech laid stress on the necessity of educating the public to the many domestic uses to which electricity can be put. The demand is certain to increase as the points of supply are multiplied and the price per unit reduced. It can nearly always be used economically for cooking and in many cases for heating. If the price of electricity be sufficiently reduced, chimneys will be a relic of barbarism. This Bill should give electrical engineers a great opportunity of showing how greatly they have benefited by the scientific and technical researches carried out since the War. The maximum water power available to us is only about a tenth that required for our industrial needs. Looked at from the electrical point of view, Britain is a very compact country with plenty of fuel available for many years to come. We look to our engineers to control the forces of Nature to further the welfare of the nation.

The Life of the Salmon.

The Salmon: its Life Story. By W. J. M. Menzies. Pp. xii+211+36 plates. (Edinburgh and London: William Blackwood and Sons, 1925.) 21*s.* net.

PROBABLY there is no vertebrate animal, except the eel, whereof the secret of its life-history has yielded so recently to systematic observation and research as the Atlantic salmon. Just as in 1896 Battista Grassi succeeded in demonstrating that the small marine fish previously classed as Leptocephalus was none other than the alevin of the eel, so in 1840 did John Shaw, gamekeeper at Drumlanrig, by confining a number of parr, hitherto accorded specific rank by ichthyologists as *Salmo salmulus*, prove that they assumed the seasonal smolt livery before being released to descend to the sea, whence they should return as *Salmo salar*.

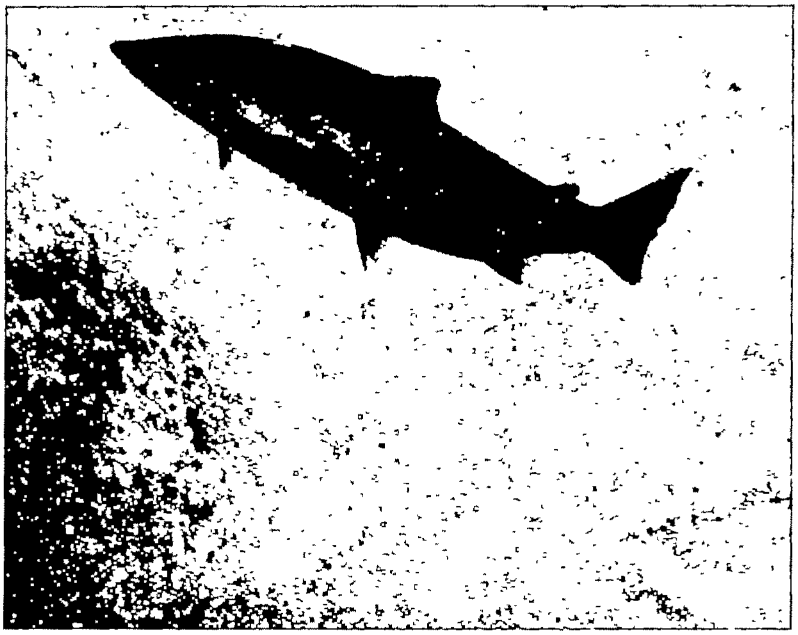

FIG. 1.—Salmon jumping at Ballyshannon Falls, R. Erne, Ireland. From "The Salmon: its Life Story."

That marked an important advance in our knowledge of one of the most valuable food-fishes; but many years passed without any further progress being reported. So late as 1886 we may read in the ninth edition of the "Encyclopædia Britannica" a statement that the smolts increase so rapidly in size after reaching the sea that they return *in the same year* as sexually mature salmon. "It is surprising," is the writer's naive comment, "that a smolt weighing only a few ounces should increase to 3 or 4 or even 6 lb. in about three months."

It was not until 1904 that Mr. H. W. Johnston announced his discovery that the age of every salmon was automatically registered on the hyalo-dentine surface of every scale on its body. This fresh light, combined with the result of marking some 6500 smolts in the Tay, as undertaken jointly by Mr. Calderwood, Salmon Fishery Inspector for Scotland, and the late Mr. P. D. Malloch of Perth, followed by the recapture of a small percentage of the marked fish on their return to the river, has redeemed from all doubt the chief facts in the life-history of the salmon. The conclusions registered have been confirmed by observations in many other rivers, notably by those conducted by Mr. J. Arthur Hutton in the Wye of Hereford.

In "The Salmon: its Life Story," Mr. W. J. M. Menzies has undertaken to summarise these conclusions and to describe for the general reader the method by which they were attained. As Assistant-Inspector of Scottish Salmon Fisheries, he has borne an active part in the marking and recapture of salmon and in registering the results. His narrative is enriched by incidents of independent observation and illustrated by many photographs. Among the latter must be noted one serious omission, namely, that in none of the numerous figures of salmon scales is there any indication of scale in another sense, although all are shown many times larger than life. This is specially perplexing, because the illustrations of smolt scales are not made from scales taken from smolts, but represent only the central portion of the scales of adult fish.

The scales of a salmon do more than merely registering its age and periodical intervals of fasting; the spawning crisis also is indicated by the peculiar scar which may be seen four times repeated in Fig. 2. Recognition of the spawning scar has revealed the fact that, although salmon may and do spawn as grilse and at any subsequent age, it is but a small percentage that do so more than once.

"Investigations in the east coast rivers, as well as in catches taken in the coast nets, have shown that in the total catch of the season the proportion of previously spawned fish is very seldom more than 5 per cent., and, on occasion, may be less than 2 per cent. The exact proportion varies from year to year, but in general is in the neighbourhood of 4 per cent."

Observation on this point has been chiefly conducted hitherto on the east coast of Scotland. Such investigation as has been effected on the western seaboard indicates a much larger percentage. It was found that among the large number of salmon taken in the Add of Argyll, no less than 34 per cent. had previously spawned. The effort of spawning greatly exhausts the fish, far more among the males than the females, the majority of the former dying before reaching the sea. The spawning mark on the scales is caused by the total absorption of the margin of the scale, during the sojourn in the river, the whole muscular fabric of the fish being also seriously depleted and deteriorated. It is remarkable that simultaneously with this depletion, the jaws of the male salmon should be greatly prolonged, a great hook being formed on the lower jaw fitting into a corresponding socket in the upper jaw. The purpose of this peculiar growth has been the subject of much speculation without any approach to explaining it.

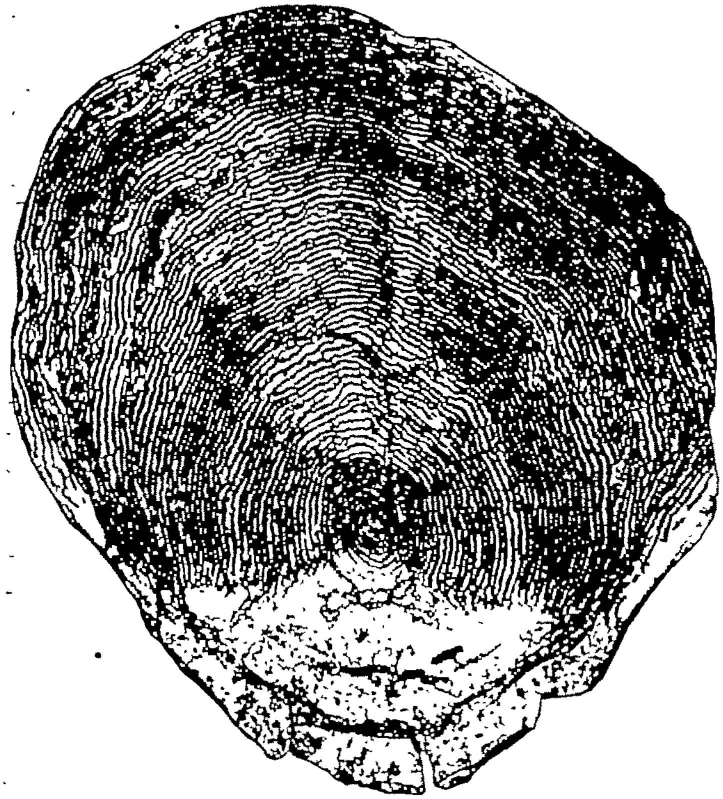

FIG. 2.—Scale of a salmon which spawned four times. From "The Salmon: its Life Story."

No question is more frequently—often hotly—discussed among anglers than whether the salmon feeds in fresh water after its return from the sea. As a parr, of course, it has to rely upon river fare; but rivers, especially Scottish rivers, provide no food sufficient to nourish lusty adult salmon, which, it must be remembered, frequented them in incalculably greater numbers before the stock had become decimated by netting and other modes of capture. Like every other scientific observer, Mr. Menzies holds strongly the opinion that a salmon fasts as soon as it leaves the sea, often, indeed, before doing so if hindered by drought or other impediment. Among other instances he quotes the result of investigation conducted in the Tweed, where it was found that out of 1442 salmon taken in the estuary, 128 (9 per cent.) contained remains of food in their stomachs, whereas none among 257 taken higher up the river retained any trace of food in stomach or intestine. It may be long before fishermen will agree in acquitting hungry-looking kelts of cannibalism; it will be longer still before suspicion will be confirmed by discovering remains of food in their stomachs or intestines.

Mr. Menzies has contributed a most useful and convenient review of the recent advance in knowledge of the life-history of the salmon, rendered possible by Mr. Johnston's discovery and interpretation of scale-marks and carried into effect by the systematic vigilance of the Fishery Board of Scotland.

HERBERT MAXWELL.

A New Survey of Architecture.

Architecture. By Sir Thomas Graham Jackson. Pp. xi + 366 + 111 plates. (London: Macmillan and Co., Ltd., 1925.) 25*s.* net.

THIS compact and well-produced volume on the growingly popular subject of the art of building is the work of no less an authority than the late Sir Thomas Jackson, Bart., R.A. The manuscript, fortunately, was completed before his death, and this posthumous book is the last from his facile pen. It is stated in the preface that "it is hoped that the book may act as an incentive" to the reading of his greater works, "Byzantine and Romanesque Architecture," "Gothic Architecture," and "The Renaissance of Roman Architecture."

The work differs from a text-book in the ordinary sense, for it is not a complete study of past art; it does not profess to be a history of architecture pure and simple. It is in no way a general essay on architecture, and though larger than a handbook is less comprehensive than a text-book; it is rather a critical study and summary of special periods, and is of a suggestive nature, which should stimulate thought and study. The work of the ancient nations of Egypt, Mesopotamia and Persia is practically omitted, and very little is said even as to the Greek and Roman styles; one chapter suffices to deal with the earlier work of each. It concentrates chiefly upon the subjects treated in the author's earlier works. It is a searchlight thrown upon certain phases of architecture.

This pleasant book is written in an easy narrative manner—a method of treatment which is all the more noticeable when a number of more or less independent styles and buildings are dealt with in rapid succession. It should convey, even to a reader little acquainted with the subject, a clear and comprehensive idea of the best buildings of the different types discussed. The illustrations, which include excellent half-tone photographs and some characteristic sketches by the author, with a few plans and elevations, are well distributed throughout the letterpress. The author has recognised that even in a general summary it is essential to show the structural motives and principles of building, before the external or internal design can be appreciated; this is clearly shown by the brief but helpful explanations of constructional expedients, such as the use of "orders" or rings of an arch in Romanesque and the construction of the vault in Gothic architecture.

Perhaps the most interesting features of the book, however, are the critical essays forming the introduction and epilogue. In the former the vexed question, "What is Architecture?" is courageously considered, and the author insists again that the true nature of architecture "does not consist in beautifying building, but on the contrary in building beautifully, which is quite another thing."

In a new work one looks to see what is said as to loubtful or disputed matters, and in this connexion it is nteresting to find that the pointed arches at Fountains Abbey and Worcester Cathedral are quoted as among he earliest in England, while the famous pointed vault at Durham is relegated to a date twenty-five years later han has been commonly assigned to it. There would appear to be few errors of fact, but the Parthenon plan should show solid walling between naos and Parthenon proper, as the openings, according to Prof. E. A. Gardner, were not part of the original design. Again, he plan of Westminster Abbey attributes the ritual hoir, or eastern part of the structural nave, to the eign of Edward I. instead of to the later years of Henry III. (1260–69). The chronological chart, showng the chief buildings in the different countries arranged n parallel columns, is useful, and there is a good index, ut no glossary.

In conclusion, it may be said that this work on rchitecture has a certain character all its own, which lly justifies its publication. One book may have a echnical, another a social, and another a religious bias, ut this is distinctly human in nature in its treatment f monarchs, patrons and architects who have played their part in the architectural drama. The epilogue is suggestive, in its description of all architecture as either "bond" or "free"—that is, either rigidly confined to a prescribed formalism, or freely adaptable to the genius of the individual. It is clearly emphasised that it depends on this generation to determine the quality of the architecture of the immediate future, and to have a care that the architectural needs of our time are met, in the words of the author, not by "beautifying building" but by "building beautifully," so that the art of man may go hand in hand with Nature in producing beautiful effects.

BANISTER FLETCHER.

Higher Geometry.

(1) *Principles of Geometry.* By Prof. H. F. Baker. Vol. 4: Higher Geometry; being Illustrations of the Utility of the Consideration of Higher Space, especially of Four and Five Dimensions. Pp. xvi + 250. (Cambridge: At the University Press, 1925.) 15*s.* net.

(2) *Géométrie du compas.* Par A. Quemper de Lanascol. Pp. xx + 406. (Paris: Albert Blanchard, 1925.) 24 francs.

(1) IN 1873 Darboux published his interesting book, "Sur une classe remarquable de courbes et de surfaces algébriques," in which he obtained properties of bicircular quartics, including as particular cases Cartesian ovals, the limaçon and the cardioide, by projection from the curve of intersection of two quadrics. But going on to the corresponding properties of quartic surfaces with a double conic, the cyclides and the anchor-ring, he found it necessary to remark: "Comme on n'a pas d'espace à quatre dimensions, les méthodes de projection ne s'étendent pas à la géométrie de l'espace."

The day has now long gone, we hope, since it was necessary to avoid the use of space of more than three dimensions in order to obtain results in ordinary space; at any rate, Prof. Baker's fourth volume will convince any one of the enormous power of the method. To obtain, from a single configuration in four dimensions, and that so simple, four arbitrary straight lines or, alternatively, six arbitrary points, practically all the surfaces and constructs about the properties of which anything at all is known, the Kummer surface, the Weddle surface, the tetrahedral complex, etc., is surely a remarkable achievement. Again, the quadric in five dimensions, as remarked by Cayley and Klein and examined in more detail by Segre, gives an immediate and much simplified account of that somewhat complicated discipline "line geometry."

The method of projection from higher space can, of course, be applied to more elementary theorems.

Propositions of one-dimensional geometry, of ranges of points upon a straight line, can be made simpler and less algebraical by considering the line as derived by projection from a conic, or, more generally, from the normal curve of order n in space of n dimensions. Circle geometry in the plane, with all its complication and apparent haphazardness, appears as an ordered whole when regarded as obtained by projection from the geometry of plane sections of a quadric. The reviewer well remembers his astonishment when it was first pointed out to him, in lecture, that Wallace's theorem of the common point of intersection of the four circumcircles of the triangles formed by four straight lines was essentially the same, from this point of view, as the theorem about Möbius tetrads, mutually inscribed and circumscribed—a proposition involving only points, lines, and planes. Also the theorem of the Hart circle of three given circles, which is such that the four circles are all touched by four other circles, becomes much more interesting and instructive in three dimensions.

All this, and very much more, is packed into the 244 pages of this volume. The book naturally suffers from the compression and is not one to be read in an arm-chair; indeed, any one page will furnish matter for several hours' cogitation by the ordinary mortal. But it is a fascinating study, and British mathematicians may well be proud of such a splendid mine of geometrical lore as is to be found in the four volumes of "Principles of Geometry."

(2) The "Géométrie du compas" of M. Quemper de Lanascol is a book of quite another kind. There is a mathematical interest in showing that every geometrical problem which can be solved by ruler and compasses can be solved by compasses alone, but this is not a difficult matter. One has only to show that (*a*) the point common to two straight lines and (*b*) the points common to a straight line and a circle, where a straight line is given by two of its points, can be found without a ruler and the thing is done. Alternatively, one can proceed by the method of Adler, by showing how to find with compasses only the inverse of a point with respect to a given circle, and remarking that we have then only to invert the ordinary construction with ruler and compasses, which involves straight lines and circles, to get a construction involving circles only. For an adequate account of both methods reference may be made to the article by E. Daniele in "Questioni riguardanti le matematiche elementari" (1914), t. 2, pp. 25-48; Coolidge in his "Treatise on the Circle and the Sphere" does the whole thing in a couple of pages (pp. 187-8).

But Mascheroni, whose "Geometria del compasso" (Pavia, 1797) is the *locus classicus* of the subject, did not confine himself to the theoretical aspect. He maintained that the practical difficulties of making a perfectly straight edge rendered it important to avoid the use of such an instrument, and his book is filled with ingenious constructions, as simple as may be, for all the problems of elementary geometry, obtaining each point of the figure as an intersection of two circles. He also gave approximate constructions, by the same means, for problems of higher than the second degree and for transcendental problems, the duplication of the cube, the quadrature of the circle, and so on.

The present volume contains all that is in Mascheroni and, in addition, gives a section on inversion. The material has been rearranged, much new matter has been added, from various sources, and the result is a great improvement on the prolixity of the "bon abbé." The book will appeal to the mathematical amateur who delights in what the author deprecatingly terms "une sorte d'acrobatie géométrique," especially when he reads how Napoleon lectured his band of savants on this very subject, evoking from Laplace the remark: "Nous attendions tout de vous, général, sauf des leçons de mathématiques." F. P. W.

Our Bookshelf.

Male Infibulation. By Eric John Dingwall. Pp. vii + 145. (London: John Bale, Sons and Danielsson, Ltd., 1925.) 10*s*. 6*d*. net.

THIS work is the first volume of a series which the author is undertaking in connexion with some of the more obscure customs of antiquity and the Middle Ages related to the sexual life of man. The book consists of three chapters dealing respectively with three forms of the practice to which the term infibulation has been applied, namely, the Roman form, the Greek form, and phallus curvatus. In the Roman form, where alone the term is applicable, a ring or similar object is attached to the prepuce. The operation was chiefly performed on singers, musicians, and slaves, the principa object being to preserve the quality and tone of the voice, which was supposed to be corrupted by sexual indulgence, while the subsidiary reason was to preven masturbation. In the Greek form, which was principally adopted by athletes and is represented on Greek statues and vases, the practice consisted in tying up the prepuce with a small band, either because the Greek were ashamed of a short foreskin associated with uncovering of the glans, or because they believed that physical strength could better be preserved in this way The phallus curvatus, which is often depicted on th vases and statues of antiquity, especially among the followers of Dionysus, the Sileni, and Satyrs, and was by no means uncommon among revellers and caricatures is regarded by the author as symbolic of a life of sexua excess, and therefore as having no possible connexio with infibulation. The work, which has obviousl involved an immense amount of literary and artisti research, is a valuable contribution to the sexuologica department of anthropology.

Dairy Engineering. By John T. Bowen. (Wiley Agricultural Engineering Series.) Pp. xiv+532. New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1925.) 18*s.* 6*d.* net.

THIS volume deals with the principles of engineering and their application to dairy practice. The method of presentation is clear and the subject matter well arranged, so that the book will serve as a useful and trustworthy guide to the dairy engineer, and also as a text-book to the student of dairying.

After a preliminary chapter on definitions, the subject of great importance in dairying—namely, the raising and application of steam—is dealt with. First the boiler and its fittings; then combustion and firing; then control of the air supply, which is an important factor in the economical use of fuel. The types of steam engine usually employed are described and their advantages and disadvantages discussed. As a proper arrangement for the carrying of steam to the different appliances is not infrequently overlooked in designing a factory, the chapter dealing with steam piping and accessories is of special interest. Attention is also directed to the advantage which is gained by the use of exhaust steam, as by its employment much can be done in dairy practice.

The chapters dealing with refrigeration and insulation are good, but no detailed consideration is given to uch operations as pasteurisation or cream separation. The internal combustion engine and various types of lectric motors are considered in detail so far as heir applicability to the dairy factory goes. The dvantages and disadvantages of electric power are also discussed. There is a chapter on temperature measurement and control.

dmiralty Handbook of Wireless Telegraphy, 1925. Prepared by Capt. W. G. H. Miles. Pp. viii+547. (London: H.M. Stationery Office, 1925.) 5*s.* net.

HE style of this book is lively and spirited and the nformation conveyed is clear and accurate. It is eant for the information and guidance of officers and en of H.M. fleet, and the editor is to be congratulated n making the subject so interesting. The modern heory of electricity is first described, and so the theory f thermionic tubes follows very convincingly later on. esonance is first described analytically and then lustrated by what happens in daily life. We are told “walk across a room carrying a cup of tea, and ote . . .” The “jar”—the Service unit of electro-atic capacity—which equals the 900th part of the icrofarad, is much in evidence and so also is the mic” (the microhenry). W/T and R/T seem to be e contractions used in the Navy for wireless tele-aphy and radio telephony respectively, and this book oves that they are very convenient.

There are one or two slips that might be altered with vantage. The lines of magnetic force round two rallel wires carrying equal currents flowing in op-site directions are circles and have not the oval ape shown in Fig. 18. The modified type of urier series, also, shown on p. 439, will certainly t represent any kind of wave form. But these are ry small matters. Considering its value it is a very eap book, and can be strongly recommended.

The Extra Pharmacopœia of Martindale and Westcott. Revised by Dr. W. Harrison Martindale and W. Wynn Westcott. Eighteenth edition. Vol. 2. Pp. xlii+728. (London: H. K. Lewis and Co., Ltd., 1925.) 20*s.* net.

WHEN “Martindale” was divided into two volumes on the issue of the fifteenth edition in 1912, the dividing line ran roughly between drugs used in the treatment of disease, which were dealt with in volume 1, and an account of recent therapeutical research which, with much bacteriological, analytical, and other information of value to medical men and pharmacists, composed volume 2. This arrangement, which has proved convenient in practice, is still maintained, and as this is the third edition published since the division took place, it is clear that in its new form the book has lost none of its popularity.

Only those familiar with the enormous output of work, of very varied quality, in therapeutics and the associated sciences, can have any idea of the trouble expended by the authors in selecting material for inclusion, and of the labour necessary for the presentation of the approved data in the highly condensed form with which users of this book have become familiar. These two features are as characteristic of this edition as of its numerous predecessors.

The senior author will have the cordial sympathy of all his readers in the loss of his collaborator, Dr. Wynn Westcott, who died at Durban on July 30, 1925, while this edition was in the press.

Grundlinien zur Entwicklungsmechanik der Pflanzengewebe. Von Dr. H. Pfeiffer. (Abhandlungen zur theoretischen Biologie, Heft 20.) Pp. vi+99. Berlin: Gebrüder Borntraeger, 1925.) 6 gold marks.

A GREAT deal of this small volume on a particular branch of “theoretical biology” will be too theoretical for the average biologist. It seems doubtful whether long Latin terminologies and chapters on such subjects as “Die erkenntnistheoretische Begründung der Entwicklungsmechanik pflanzlichen Gewebe” really advance the subject appreciably.

Later chapters, however, are of interest, especially where they treat of recent work in this field, which is such a complex one, and so different in many ways from the corresponding field in animals, that every attempt to summarise and sift critically the materials is bound to be of service. We hope that Dr. Pfeiffer will follow this up by a further volume on the achievements rather than on the theoretical bases of this branch of science.

Mesopotamia: the Babylonian and Assyrian Civilization. By Prof. L. Delaporte. (The History of Civilization Series.) Pp. xvi+371. Translated by V. Gordon Childe. (London: Kegan Paul and Co., Ltd.; New York: Alfred A. Knopf, 1925.) 16*s.* net.

THIS is a quite useful summary of present knowledge of the subject, including a short history of each region, and chapters on its institutions, religion, economic and social structure, and contributions to knowledge. There are a number of small line drawings of typical works of art. The translation is not very happy in places, and there are some odd mistakes.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Transmutation of Elements.

IN a letter to NATURE of January 2, 1926, Prof. Smits records the obtaining of evidence of the transmutation of lead into thallium and into mercury. One of our research students has been employed for some time in an attempt to detect the transmutation of lead into thallium, but up to the present the experimental difficulties have not been satisfactorily overcome, and we are not yet able to make a definite statement on the matter as a result of this work. The experiments so far attempted in this Laboratory, and those contemplated in future efforts, have been designed to facilitate the entry of an electron into the nucleus of a lead atom in the hope of effecting a transmutation into an isobare of another element (thallium), rather than to bring about a transmutation by the ejection of a proton or an α-particle from the nucleus of the lead atom.

We may perhaps be permitted to review the results of attempts at transmutation of elements which have been recently recorded in the light of these two alternative possibilities. In the case of the transmutation of mercury (atomic number 80) into gold (79) which has been announced by Miethe and Stammreich, and independently by Nagaoka, the change might conceivably be effected either by the entry of an electron into, or by the removal of a proton from, the nucleus of the mercury atom. The same alternatives present themselves in regard to the transformation of lead (82) into thallium (81).

Prof. Nagaoka, in attempting to bring about the transmutation of mercury into gold, designed his experiments with the view of facilitating powerful disturbance of the mercury nucleus which might lead to the ejection of a proton, because considerations of the satellites of the spectral lines of mercury had led him to the conclusion that in this element a proton is "slightly detached" from the central nucleus, and therefore possibly capable of removal. His experiments, which yielded a positive result, do not, however, enable us to distinguish conclusively between the two alternative methods of transmutation.

In Miethe and Stammreich's experiments the arrangement was entirely different, and the gold was obtained from mercury-vapour lamps using a heavy current, but requiring that the potential difference should exceed only 170 volts. In the account of these experiments given in NATURE of August 9, 1924, the possibility of the transmutation being due to the disruption of the mercury nucleus appears to be the only explanation considered; but, as Prof. Soddy has pointed out, an atomic disruption is not necessarily involved, and the alternative of attaching an electron to the mercury nucleus needs to be taken into account. Certainly the nature of the experiment does not preclude this possibility.

In essentials the experimental arrangement employed by Smits was similar to that of Miethe, for it consisted of a quartz lead-vapour lamp of special design run at voltages of less than 100 and with currents up to 100 amps. Smits records that initially the spectrum showed only one of the mercury lines, 2536, and that very weakly, but that after running the lamp for 10 hours the strongest mercury lines in the visible as well as the ultra-violet region of the spectrum had made their appearance, and that the most characteristic thallium line was also visible.

Now in the case of the transmutation of lead (82) into mercury (80), the change may occur either by the intermediate production of thallium by one of the processes already suggested, and the subsequent conversion of the thallium into mercury by a second similar process, or it can occur as a one-stage change by the ejection from the lead nucleus of either one doubly charged positive particle (presumably an α-particle) or two singly charged positive particles (presumably protons) simultaneously. If the process occurs by the intermediate production of thallium, one would expect to find evidence of a relatively large amount of thallium compared with the amount of mercury produced. Prof. Smits does not appear to have found such an effect, for he records stronger evidence of the production of mercury than of the production of thallium.

In the circumstances of Nagaoka's experiments, in which very intense electric fields were employed, it is conceivable that these fields brought about a disruption of the nucleus, and that, as a result, a portion of the nucleus was thrown off. In the cases both of Miethe's experiment and of Smits' experiment, if such a disruption occurs, it must be brought about by a different means. When atoms are bombarded by electrons, it is possible that in a few instances an electron penetrates within the *K* shell of extra-nuclear electrons, though it is certainly surprising that this is possible in the circumstances of these experiments. When such a penetration does occur, the electron will be attracted towards the nucleus and may possibly be absorbed by it. Even so, in some cases the absorption of an electron by the nucleus may render the latter unstable and disruption may occur with the ejection of a proton and an electron, either separately or together, in which cas the final chemical state of the disturbed atom will b the same as if the electron had been absorbed by th nucleus and a stable condition attained.

If we adopt Nagaoka's view that there are "slightl detached" portions of the nucleus, disruption b the approach of an electron is perhaps more easil imagined. Moreover, since lead consists of severa isotopes, it is not unreasonable to suppose that th close approach of an electron to the nuclei of differen lead isotopes would have different results. It possible that the production of thallium results from on isotope, and the production of mercury from anothe

It must be remembered that if the transmutatio of one element into another is brought about by th ejection of some part of the parent nucleus, somethin corresponding to the final state of the ejected portio must be present to the same extent as the elemen resulting from the changed condition of the main pa of the nucleus of the parent atom. In the cas considered, if the thallium and mercury are produce in this way, one might expect to find hydrogen (perhaps in the latter case, helium) present to corr sponding extents, and it is possible that these mig be detected by spectroscopic observations und appropriate conditions.

In the case of transmutation by absorption electrons into the parent nuclei, one would not expe to find these other elements. It therefore appea that the most hopeful method of obtaining eviden as to the exact nature of transmutations such those recently recorded is from attempts to dete the lighter products as well as the heavier produ of possible transmutations.

A. C. DAVIES.
FRANK HORTON.

Royal Holloway College,
Englefield Green, January 7.

Foreshadowing Elements of Atomic Numbers 75, 85, 87, and 93 by means of X-rays.

IN your columns of Current Topics and Events, Dec. 26, 1925, p. 943, I notice a critical abstract of a series of articles by Dr. Druce and myself, relative to the existence of elements of atomic numbers 75, 85, 87, and 93, which appeared in the *Chemical News*, Oct. 30, Nov. 6, 13, 20, and 27. A later communication in the issue of Dec. 11, 1925, should be included, as reference will be made to it below.

In justification of our work I must state that Film No. 3, which gave us the evidence of the presence of element 75 and meagre evidence of the presence of element 87, is completely ignored in the critical argument in question. Manganese sulphate was used in this case.

The line on which we have attempted to establish element 87 (Film No. 3) is one of wave-length 1·032, a fairly strong line considering the range of exposure; not $\lambda = 1{\cdot}040$, because this line seemed to represent some other element, and in one case it was wide enough to include several lines ($\lambda 1{\cdot}040$ was, however, mentioned in this connexion, and I tried to make something of it, as an attempt was made by Dr. Druce to isolate element 87 chemically from pyrolusite, but this substance has, as regards this element, so far proved to be disappointing). On p. 289 of the *Chemical News* we say: "On investigation we find that this line of wave-length 1·032 Å units fell exactly between the theoretical $L\alpha_1$ and $L\alpha_2$ lines of element of atomic number 87. We looked for the $L\beta$ line of this element, but failed to find it, as the bromine-silver absorption bands on the film fell in the region where the line should appear as a very faint one." In the same journal for Dec. 11, 1925, this obscured line was indicated as it was seen by one of Messrs. Adam Hilger's research staff when I was examining the film on one of their spectrum comparators.

Had mercury been present sufficient to give rise to an L radiation, the whole of this radiation would have been excited at the voltage used, and the comparatively strong Hg$L\beta_1$ line would have appeared on the film; whereas, only the lines corresponding to the $L\alpha_1$ and $L\beta_1$ radiations of 75 were present, in addition to those mentioned above of wave-lengths 1·032 and 0·837 (the latter as afterwards approximately determined by means of the spectrum comparator). The three lines were of sufficient strength to stand out well on the film, which was clear and free from fogging and other obscuring effects, except in respect of the Br-Ag absorption region.

Referring to p. 339 (Nov. 27 issue of the *Chemical News*), Film No. 1 was not perfect throughout and the exposure was more on the long wave-length side, but the 1·43 line was clearly revealed. Film No. 2 showed fairly strong lines $\lambda = 1{\cdot}43$ and $\lambda = 1{\cdot}233$, but the range of oscillation was limited to the region where these lines fell. Film No. 3, therefore, afforded a crucial test, for it covered the range below $\lambda = 0{\cdot}837$ to that beyond $\lambda = 1{\cdot}539$. When this film was taken, two other films were consecutively obtained with the same exposure (6 hours) and the same range of oscillation of the crystal and the same setting of the spectrograph. One showed only the copper lines, and it was a perfect film in every way. The other showed only the $K\alpha$ and $K\beta$ lines of both zinc and copper, for a substance containing zinc had been rubbed on the copper anticathode. Two of these sets of lines on their respective films were used to check the 75 $L\alpha_1$ line on one of them by noting the displacement of this line relative to that of the $K\alpha$ line of zinc, using for this purpose the spectrum comparator mentioned above. The copper lines were used for registration in the usual way. This test showed a slight displacement of the line towards the shorter wave-length side relative to that of zinc.

Furthermore, had mercury been the cause of one of our lines in the above tests, the Hg$L\beta_1$ line should have appeared on these three films and the Hg$L\alpha_1$ line as well on the films containing the zinc and copper lines only, but no sign of these lines could be detected. All three films were clear and the copper lines were quite strong, as were the zinc lines in the one case where a zinc compound was placed on the anticathode as stated above.

Films Nos. 4 and 5 were taken, when a sample prepared from pyrolusite was rubbed on the face of the anticathode. Lines $\lambda = 1{\cdot}086$ and $\lambda = 0{\cdot}895$ were obtained corresponding very closely with the $L\alpha_1$ and $L\beta_1$ lines of element 85, which we commented upon thus: "They are too ill-defined for us to establish their identification with this possible element." Pyrolusite samples have so far given a number of lines we could not identify. In two cases "93" appeared to be foreshadowed, but we dismissed this matter in the following terms. "The last element of all, of atomic number 93, was discussed in our first communication . . . the possibility of this element existing having stimulated our research from the start. There is some evidence of its existence, but to be critical, the line 0·693 comes near to the limit of the region explored by the setting (oscillation) of the rocksalt crystal of the spectrograph, and edge effects are possible here. At any rate this may account for some of the extreme 'lines' given at the foot of columns 12 and 13"—p. 340, *loc. cit.* It is true another likely pair of lines of wave-lengths 0·888 and 0·897 appeared on another film, but we still hold the same view that 93 is too imperfectly foreshadowed to be seriously considered. The calculated wave-length of the $L\alpha_1$ line of 93 I find to be 0·8877.

With regard to the brass of the apparatus giving rise to a zinc line, Messrs. A. Hilger, Ltd., say no such line ever appeared on their films except in the case of the tungsten target, which has a brass overlapping edge that holds the target in place.

Referring to the last remark in the note in NATURE, this, in my opinion, is uncalled for, since we have placed all the cards on the table, and then say in effect "that the research we have started on the missing elements in, or in connection with, Group VII, is promising and the work is being continued." All the quotations are from our own writings as listed at the opening.

In conclusion, I only regard 75 and 87 as identified by means of X-rays, and these, so far as published, from manganese sulphate, and not from pyrolusite. Pyrolusite gives lines difficult to identify, but with manganese sulphate all the proper lines were, in my opinion, identified.

As regards the confirmatory evidence from Dr. Druce's chemical side of this research I instigated, this might be mentioned, but I must leave the chemical side to my colleague.

F. H. LORING.

WE have carefully examined Mr. F. H. Loring's part in six contributions as published in the *Chemical News*, and also the above communication, all in respect of the X-ray side of the research, and we have pleasure in stating that Mr Loring has correctly transcribed our measurements, and the statements made as coming from us are correctly so described.

ADAM HILGER, LTD.
F. TWYMAN (Manager).

THE position taken up in the note to which Mr. Loring's letter refers was that the X-ray evidence was insufficient definitely to establish his claims. Experience with apparatus similar to that used by Mr. Loring shows that the difficulty is not one of obtaining foreign lines but of eliminating them. Unless special precautions are taken, prolonged exposures give lines due to various sources in addition to those corresponding to the radiations from the anticathode. Two of the most common sources are zinc and mercury. If the exposure and conditions are such as to permit of the detection of small quantities of any element in the anticathode, then the zinc line must appear from the passage of the X-rays through the brass slit of the spectrometer and probably also from the brass of the tube itself. If we accept Mr. Loring's view that the line 1·43 is not the zinc $K\alpha$ line, then the necessary conclusion is that he could not hope, under the conditions of his experiments, to detect small quantities of elements in the material under investigation. The photograph to which reference was made in the note was made for the purpose of that note and showed both zinc and mercury lines.

Mr. Loring states that a comparison of the line 1·43 with the zinc $K\alpha$ line obtained on another film showed a slight difference in position between the two. It is possible to suggest various explanations for such a shift based on purely geometrical considerations, but a critical discussion of the point is impossible until a detailed account of the experimental arrangements is published. A better test would be to obtain both lines on the same plate. If the amount of element No. 75 present is so great that the $L\alpha_1$ and $L\beta_1$ lines appear with exposures insufficient to bring up the zinc line, then it should be relatively easy to obtain also the γ_1 line, which lies well outside the bromine absorption band.

The results claimed by Mr. Loring are so important that the X-ray identification of the lines should be placed beyond doubt, and this cannot be said to be the case until a satisfactory explanation is given of all the lines found on the films, and not merely of a selection of them, as has been done up to the present.

THE WRITER OF THE NOTE.

Genes and Linkage Groups in Genetics.

I FIND it a little difficult to deal with Prof. MacBride's reply to my letter, in NATURE of December 26, since it seems to me not to take any account of the numerous facts bearing on the point which I raised. I feel that the only course is very briefly to enumerate the chief of these facts, and leave other biologists to judge if Prof. MacBride is right in his strictures, or in his views of linkage. I do this at the risk of becoming tedious, because it appears to me very unfortunate that, when delicate quantitative methods are at length introduced into a difficult biological field, they should be attacked on what I consider wholly insufficient grounds by prominent authorities such as Prof. MacBride.

As I see them, the facts are these: (1) There are numerous pairs of characters of organisms which "breed true" and which, when the strains showing them in pure form are crossed, reappear in the F_2 generation in the ratio 3 : 1. This has universally been taken to indicate material *somethings* in the germ-plasm connected with the appearance of the characters in question, and segregating in a clean-cut way into the F_1 gametes—in other words, *genetic units*. These doubtless are "disturbances of the chromosomes," but they are equally genetic units, and we may continue to use the non-committal term *factors* for them.

(2) When two such pairs of factors (call them A and *a*, B and *b* respectively) have been separately identified in a species, we can then test them together in one experiment. If so, it is without exception found that one of two things will happen:—

(2*a*) However the factors are introduced into the cross, the results in all later generations are the same. The F_2 gives the ratio $9AB : 3Ab : 3aB : 1ab$, the back-cross to the double recessive the ratio 1 : 1 . 1 : 1. This has been universally taken to imply *independent segregation* of the two factors.

Or (2*b*), the result is different according as to how the characters are introduced into the cross. Taking, for simplicity's sake, only the result of back-crossing F_1 to the double recessive, then (i.) if the cross was $AB \times ab$, we get $nAB : 1Ab : 1aB : nab$, where $n > 1$. (ii.) If the cross had been $Ab \times aB$, precisely the *reverse* result occurs, namely, $1AB : nAb : naB : 1ab$, *n* having the same value as before. This has been universally taken to indicate genetic linkage (some degree of absence of independence) between the two factors. (iii.) In Drosophila there is the further fact that the results under (i.) and (ii.) differ according to the sex of F_1. The female gives the formula stated above, but the male, without exception, gives *n* infinite—*i.e.* linkage is complete in the male. How these facts bear any relation to Prof. MacBride's definition of linkage, I fail to see. The same factors in the same proportions are present in F_1 in both (i.) and (ii.), and in male and female under (iii.); yet the proportions of the normal type and what Prof. MacBride regards as the doubly pathological type (with both mutant characters) are entirely different in accordance with the way in which the factors entered the cross, and with the sex of the individual tested. That this reversal of proportions can have anything to do with the weakening of developmental energy of which Prof. MacBride speaks as the basis of linkage, is to me unintelligible.

(3*a*) Finally, we can define as the "percentage cross-over value" (N.B., *pace* Prof. MacBride, as a purely genetic concept, with *no reference* to possible cytological interpretation) the expression $\frac{100}{n+1}$.

(3*b*) If by the methods of (2*b*) above, A or *a* has been found to be linked with B or *b* with cross-over value *p*, and with C or *c* with cross-over value *q*, then it can now be prophesied that on testing B or *b* with C or *c* (α) linkage will be found between them; and (β) if *p* and *q* are small, the cross-over value will be the algebraic sum of $p \pm q$.

This prophecy has been repeatedly verified; and no exceptions occur to the rule, provided naturally that conditions are kept constant, as in any physical or chemical experiment. It is on this last general result that the hypothesis of linear arrangement of the factors is based. I can only repeat that if Prof. MacBride can advance any alternative explanation of these facts (which he has not yet done), it will be of great interest.

With regard to points in Prof. MacBride's reply, he is not accurate in stating that Jennings started by assuming chromosome-breakage. Jennings assumed nothing but the facts provided directly by certain breeding experiments—namely, the proportions of certain visible characters appearing after certain crosses. The genetical fact that linkage is broken in a regular percentage of cases is entirely independent of any cytological hypothesis advanced in further explanation of it; and I repudiate the suggestion that to state this is to show confusion of thought. I have tried hard to grasp Prof. MacBride's own definition of linkage. He states that the basis of a linkage-group is "an impairment . . . [of] 'develop mental energy' "; in other words, if I understand him aright, a kind of constitutional disease. Further, each of its constituent "factors" is a "symptom" of this diseased state. Hence, I take it, *Drosophila melanogaster* is afflicted with 4 of these constitutional diseases, of varying severity, since some exhibit many more "symptoms" (factors) than others. *D. obscura*, on the contrary, suffers from 5 such "diseases," and *D. virilis* from 6. Whether the greater intensity of linkage in the males indicates a greater severity of affection, I do not gather. I repeat that this is the only meaning that I can extract from his words; if I am mistaken, I apologise. Prof. MacBride also states that a unit-factor is a *change*, which to me is unintelligible. He also indulges in some speculations about the origin of mutations. This, however, has nothing to do with the point I raised, namely, the distribution of segregating factors, by whatever means originated, among the gametes.

Neither are the beliefs of Dr. Bateson or of Prof. Johannsen at issue. "What the policeman said is not evidence" holds good for science as well as for law. The facts alone concern us, and I have tried to confine myself to such simple facts as with the aid of half-a-dozen stocks of Drosophila could be easily imparted by practical demonstration to a class of undergraduate students, and are regularly so demonstrated in numerous American universities.

A Metastable *P* Term in the Manganese Arc Spectrum.

THREE years ago Wentzel (*Phys. Zeit.*, 24, 104, 1923) pointed out that a metastable state of the manganese atom was to be expected and as evidence of this directed attention to a fivefold *D'* term. So far as the author is aware, *P'* terms in this spectrum have never been identified although they also should be expected.

In a letter to NATURE by Mr. Beese and me (December 26, 1925, p. 936) attention was directed to the fact, noticed by me, that in many spectra the frequency of the first *pp'* group is near to the difference of frequency between the two lowest energy levels in the same system, both in the spectrum concerned and in the spectrum of the once more ionised atom.

Dr. R. V. Zumstein, National Research Fellow at the University of Michigan, has kindly pointed out to me a group of six lines in the manganese spectrum. During Dr. Zumstein's researches on absorption in the spectrum of manganese (to appear in the *Physical Review*) these lines were found to be reversed in a heavy manganese arc but not absorbed by heated manganese vapour. These lines, therefore, must arise from low-lying energy levels in the atom but not from the normal state. Three of the lines were tentatively designated by Catalán (*Phil. Trans.* 223 A, 127, 1922) as the fifth triplet of the sharp series in what is now known to be the octet system. However, the intensities of these three lines are not in the usual order and are much too great for this assignment. The reversal of these lines in the heavy arc, while the other triplets of the sharp series are not reversed, makes it certain that Catalán's assignment is incorrect.

The above-mentioned group of six lines satisfied the relation pointed out in the first paragraph for the location of the *pp'* group, and, on examination, these six lines are found to form a normal *pp'* group. The data are given in Table I. The principal narrow triplet is the first triplet in the sextet principal series. The first triplet in the septet system of ionised manganese is seen to be actually entwined with the *pp'* group. The *pp'* group is seen to be normal in structure. The behaviour of these lines in the arc and absorption as described above is in accord with their assignment as a *pp'* group. The Zeeman pattern has apparently never been determined for this group of lines. However, there seems little room for doubt that these lines are a *pp'* multiplet in the octet system of Mn I, involving a metastable threefold *P* term. Since the *pp'* frequency is so near ${}^7S_3 - {}^7P_4$, the limit of the ${}^8P'$ terms must correspond to an ionised manganese atom excited in a ${}^7P$ state.

"Alchemistische Decknamen."

IN their recent paper under the above title (*Sitzungsber. d. Phys.-Med. Sozietät*, Erlangen, Bd. 56, pp. 17-36, 1924) Profs. Wiedemann and Ruska used (among others) the Dresden MS. 210, which contains a list of "Decknamen" for iron, copper, tin, lead, mercury and sal-ammoniac, twenty-four for each substance. It may be worth recording that a list so similar as to point to a common origin occurs in the British Museum MS. *Add.* 25724, ff. 15 *verso*-17 *recto*. This gives 24 names each for iron, copper, sulphur, tin, lead, mercury and sal-ammoniac, so that it affords a check upon Wiedemann and Ruska's list in the case of the six bodies mentioned, and supplements it with the names of sulphur, which are missing from the Dresden MS. The two MSS. agree in being anonymous, while the caption at the head of the list in the Dresden MS. is identical with that in the Brit. Mus MS.

i. *Iron.*—Names 1-5 and 7-24 are the same in both lists. The Dresden No. 6, *al adqār*, is replaced by *al-ashqar* ("the ruddy") in the Brit. Mus. MS. The latter reading appears to be preferable; I find no authority for Wiedemann and Ruska's translation of *adqār* as "Fuchsfarbige."

ii. *Copper.*—The two lists agree in all 24 names, except that the Brit. Mus. MS. reads *nāwūs* (sarcophagus) for *ṭāwūs* (peacock). It is difficult to say which is the more probable reading, though the characteristic colours of copper salts tend to favour *ṭāwūs*.

iii. *Tin.*—All the names are identical with the exception of Nos. 11 and 22. For the former, Wiedemann and Ruska read "*al qāṣirī*, das Mangelhafte." The Brit. Mus. MS. reads *al-qāḍī*, *i.e.* the judge, which is far more probable, especially as *qāṣirī* is apparently quite unknown to Arabic lexicographers For No. 22, Wiedemann and Ruska give "*al abīsmat al ḥağar* (unverstandlich; *basīmat al ḥağar* Lacheln des Steins [der Weisen] ?)." The Brit. Mus. MS. reads *ḥajar al-ishmīth*, *i.e.* the stone of *ithmid* or antimony sulphide (*kuḥl* or *στίμμι*).

iv. *Lead.*—The two lists agree in the main. Dresden No. 11, however, is given as *al sarzīn* (Wiedemann and Ruska:—"wohl verdorbenes persisches Wort"). The Brit. Mus MS. reads *al-razīn*, "the heavy, ponderous." Dresden No. 17 reads *al baḥs*; this appears to be a misprint for *al-naḥs*, since Wiedemann and Ruska translate the word correctly as *Schaden*. Dresden No. 18 reads *aḥraṣ*, rightly emended by Wiedemann and Ruska to *aḥras*, the Brit. Mus. reading.

v. *Mercury.*—Perfect agreement between the two lists.

vi. *Sal-ammoniac.*—Dresden No. 1, *al mukram*; Brit. Mus., *al-karam*. The former is preferable. Dresden No. 23 is "*al kajjis*, der intelligente"; the Brit. Mus. MS reads *al-layyin*, "the soft," which is clearly correct. Dresden No. 24 is the same as No. 22 ("*ṣābūn al ḥukamā'*, Seife der Gelehrten"), Brit. Mus No. 24 reads *shams al-ḥukamā'*, *i.e.* the sun of the sages.

vii. *Sulphur.*—Absent from the Dresden MS. The British Museum MS. reads as follows:—1. Quite definitely *al-laṭ'ī*, which is unintelligible. It may be a mistake for, or a modification of, *al-latha*, the gum or resin. 2. *al-wāqid*, the burning. 3. *al-'aqrab*, the scorpion. 4. *al-muḥriq*, the inflammable. 5. *al-nār*, the fire. 6. *al-aṣfar*, the yellow. 7. *al-sham'*, the wax. 8. *dhū al-janāḥīn*, the winged. 9. *al-ṣab'*, the indicator; but it is likely that a diacritical point has been omitted and that the true reading is *al-ṣabgh*, the dyer [*sc.*, of metals]. 10. *al-'arūs*, the bride. 11. *al-ṣamgha* (although there is no diacritical point over the *'ain*), the gum. 12. *al-khiḍāb*, the dye. 13. *al-zuḥār*, the moaner (possibly because of the crackling of a lump of sulphur when held in the hand). 14. *al-ṭalq*, the talc (mica, gypsum). 15. *al-dhahabī*, the golden. 16. *al-'alam*, the sign. 17. *al-bayraq*, the flag. 18. *al-jabal al-aṣfar*, the yellow mountain. 19. *al-ḥajar al-muṣaffaḥ*, the smooth stone. 20. *al-mubayyiḍ*, the whitener. 21. *al-musawwid*, the blackener. 22. *al-mulayyin*, the softener. 23. *zandarīkh*, sandarach. 24. *al-ḥimār*, the ass (or, since the first vowel is uncertain, the word may possibly mean "the redness." *Cf* Dozy, *Supplément, sub voce*).

Maori Rock-Carvings.

IN NATURE of November 21 last, p. 763, reference is made to an interesting discovery of Maori rock-carvings announced by the Wellington (N.Z.) correspondent of the *Times* in its issue of November 11. In that account there occurs the following passage. "Further exploration in this region [the Ngatihotu country] it is hoped may yield . . . possibly even a picture of a Moa which would establish the connexion of the Maoris or their predecessors with this great wingless bird. . . . Some authorities consider that the Moa was extinct before the first Maori migration, though it is admitted that the people who were here before the Maoris saw the bird in the flesh."

In the year 1889 it fell to me to explore the Sumner cave near Christchurch (N.Z.). The cave was concealed by a landslip (probably due to an earthquake) which had occurred before the colonisation of Canterbury Province. Its existence was quite unsuspected until the quarrying for road-mending of the stone supposed to be continuous with the live-rock of the hill of which it formed the fore-front, which had been going on for many years, suddenly broke into it On crawling in as soon as the orifice permitted, I found on the floor of the cave—a cavity fit to shelter a score of people perhaps—a fire-place with half-consumed wood projecting radially from it in an undisturbed position, just as left by the occupants who had hurriedly escaped, leaving their fire alight until it had burned out. They were evidently fisher-folk, for they left behind them fish hooks, net sinkers, paddles, numerous lengths of fishing-line of plaited human hair, and in their kitchen-midden broken shells, bones of seal, dog, Moa (partly burned, partly broken), and of other bird bones, among them those of an extinct species of swan (*Chenopis sumnerensis*) unknown to Maori tradition.

Evidence more important to the question being here considered, however, I found lying around the fire-place and in other parts of the cave, in the form of Moa egg-shells so disposed as to leave little doubt that their contents had been partaken of as a meal. Such portions of these shells as had not suffered by the fire still retained their internal membrane, indicating that the eggs when gathered were still fresh—or sufficiently so. Other objects obtained from the cave were a boat-bailer with quite characteristic Maori ornamentation, a carved curl-tailed dog (? head of a paddle), a tiki, one or two other greenstone objects, and a few obsidian flakes The cave-deposit consisted of sterile strata separated by well-marked hearths containing charcoal, shells, and fragments of bone, indicating an intermittent occupation of very long duration. The fall of material from the roof had been extremely slow since the closure of the cave, for the bailer, which lay on the surface hollow up, was practically empty. The occupants of the cave, as identified by their cultural objects, must be held to be of the same race as the present natives—unless the pre-Maoris practised a similar style of carving and of greenstone manufacture—and were obviously acquainted with the living Dinornis.

The contents of the cave were placed in the Canterbury Museum, Christchurch, of which I was then Director, and a hasty preliminary account appeared in the *Transactions of the New Zealand Institute* for 1890, less detailed, however, than the contemporary record, with photographs, preserved in my journal. My departure from New Zealand and multifarious imperious duties since have prevented the publication of the fuller details. I hope, however, with continued improvement in health, to make good my default shortly.

HENRY O. FORBES.

Luminous Leaves and Stalks from Bengal.

PROF. BULLER, of Manitoba, Winnipeg, in his "Researches on Fungi," vol. 3, published in 1924, states on p. 426 that he is now able to affirm that luminous leaves, in addition to occurring in France, Germany and Java, as reported by Tulasne in 1848 and Molisch in 1904, also occur in England, Canada, and the United States; and that as time goes on, doubtless many other countries will be added to this list.

In July last I obtained a collection of decaying leaves, small pieces of dead wood, living grass roots and stalks, living fern petioles, and living roots of

Averrhoa Carambola, giving out a distinct soft white light, from a covering of forest bed in Barisal in Bengal. Four years back I got a similar collection of luminous leaves, wood, etc., from the Bikrampur district in Bengal. In most cases I could find a colourless fungus-hyphæ in their sections. Luminosity was usually confined to certain spots only, while in some cases thin flat surfaces were luminous all over. Stalks showed a white streak of light along their lengths; no particular tissues within the stalks could be located as luminous.

Molisch attributed the cause of luminosity to fungi in decaying leaves, but so long as the fungus is not isolated and brought under pure culture so that its identity may be established, the point is not free from doubt. Molisch holds that the fungus gives out a photogen which, coming in contact with oxygen and water, gives out light; it is a process of slow chemical combustion without production of heat. But the photogen cannot be extracted. When I began crushing those luminous specimens with pestle in mortars containing a little cold and hot water in a dark room, the luminosity failed altogether, showing that photogen is not an extracellular secretion or excretion, but is bound up inseparably with the protoplasm of the living hyphæ—so long as the fungus is in a living condition it continues to emit light. The response of the light-giving substance in this case was in every way similar to that of a living one, namely, when I put those luminous specimens in a receiver and supplied them with a current of pure oxygen, they glowed more intensely than before. Light diminished on passing currents of pure hydrogen, nitrogen, and carbon dioxide gas, the former luminosity reappearing on access to the oxygen of the air. Putting specimens in a vacuum-bath and using an air-pump the light failed, but as soon as air was let in, the former condition of luminosity revived at once. Luminosity increased when specimens were immersed in dilute solution of hydrogen peroxide. Luminosity failed permanently on dipping the specimens in strong alcohol or chloroform, thus showing that if the fungus is somehow killed, there can no longer be the production of photogen.

The present lot of specimens remained luminous for about ten weeks, being kept in a moist condition. Specimens lose their luminosity when in a dried condition in blotting paper, but revive partially when in contact with water.

I could develop a photographic plate by exposing the film side to the direct action of a luminous stalk for nearly 48 hours, keeping a control.

The Origin of the Satellites in the Ultraviolet OH Bands.

IN a letter in NATURE of February 7, 1925, p. 194, G. H. Dieke suggests that the numerous satellites in the ultraviolet OH bands originate in the same quantum states of the molecules as do the main lines. The test of this supposition is to see whether or not these faint lines are additional combinations between the same terms which are given for the principal lines, but sufficiently precise measurements for the application of this criterion have not been available. I have therefore remeasured the λ3064 band, using a high dispersion plate (1·3 Å.U. per mm.) on which this band was strongly developed, the main lines being necessarily over-exposed in order that the satellite system be well brought out.

The following "satellite" Q_1 and Q_2 series which, if combined with the main P and R lines, satisfy the combination relation $Q(m) - P(m+1) = R(m) - Q(m+1)$, have been located. They must, then, have the same final rotational state as the P and R branches, and so can be represented by the term formulas $F_1(m) - f_1(m)$ and $F_2(m) - f_2(m)$ respectively. Vacuum wave numbers are given, and unresolved doublets are denoted by *.

m.	$\sigma Q_1(m)$.	$\sigma Q_2(m)$.	m.	$\sigma Q_1(m)$.	$\sigma Q_2(m)$.

It seems probable that most of the remaining satellites can also be represented by combinations between the terms in the main branches.

The same combination defect, $Q(m) - P(m+1) = R(m) - Q(m+1)$, which exists in these OH bands is also present in the magnesium hydride bands.[1] In view of the general similarity between the two band systems—both having the same characteristic spreading of the doublets near the band origins—it is reasonable to assume that the MgH bands, too, owe their combination defect to the existence of displaced Q levels. Satellite lines also exist in the MgH bands, but their investigation is obstructed by the presence of the many faint isotope lines.

These additional energy-levels have not as yet received interpretation in the theory of band spectra. More quantitative results such as the above would be a great aid in the solution of this problem.

The word satellite as used in this connexion, however, is somewhat of a misnomer, since, for example, $Q_2(24) - \sigma Q_2(24) = 2 \cdot 1$ Å.U., with five other lines falling in this interval.

The Crystal as Diffraction Grating.

THE use of a crystal as a grating for measuring the wave-lengths of Rontgen rays affords a beautiful illustration of the value of a second reference frame that may be associated with the customary reference frame of vector analysis. Let $\mathbf{e}_1 \ \mathbf{e}_2 \ \mathbf{e}_3$ be the prime vectors of the customary frame. The second or derived frame, the prime vectors of which we will denote by $\mathbf{e}^1 \ \mathbf{e}^2 \ \mathbf{e}^3$ with superior affixes, is such that the scalar products $\mathbf{x}.\mathbf{e}_1 \ \mathbf{x}.\mathbf{e}_2 \ \mathbf{x}.\mathbf{e}_3$ of any vector $\mathbf{x}$ and the original prime vectors are the cartesian components of the vector in the derived frame, and the scalar products $\mathbf{x}.\mathbf{e}^1 \ \mathbf{x}.\mathbf{e}^2 \ \mathbf{x}.\mathbf{e}^3$ of the vector $\mathbf{x}$ and the derived prime vectors are the cartesian components of the vector in the original frame.

Because of this property we use $x^1 \ x^2 \ x^3$ with superior affixes to denote the components of $\mathbf{x}$ in the original frame, and $x_1 \ x_2 \ x_3$ for the components in the derived frame, so that with the usual convention as to the summation of affixes we write

$$\mathbf{x} = x^a \mathbf{e}_a = x_a \mathbf{e}^a$$

In a crystal of any form we take the origin at a point occupied by an atom, and for the heads of the prime vectors $\mathbf{e}_1$ $\mathbf{e}_2$ $\mathbf{e}_3$ we take three adjacent non-coplanar atoms. Let unit vector $\mathbf{r}$ give the direction of the incident ray and unit vector $\mathbf{s}$ that of the emergent ray. The conditions for the reinforcement of an emergent ray of wave-length λ are

---

[1] W. W. Watson and P. Rudnick, *Astroph. Journal*, January 1926. That these bands have as their carrier the MgH+ ion is shown by several independent lines of evidence.

$$s_1 - r_1 = m_1\lambda \quad s_2 - r_2 = m_2\lambda \quad s_3 - r_3 = m_3\lambda \qquad (1)$$

where m_1 m_2 m_3 are integers.

We take a vector $\mathbf{m}$ the components of which in the derived reference frame are the integers m_1 m_2 m_3 so that

$$\mathbf{m} = m_1\mathbf{e}^1 + m_2\mathbf{e}^2 + m_3\mathbf{e}^3$$

Equations (1) are then all included in

$$\mathbf{s} - \mathbf{r} = \lambda\mathbf{m} \quad . \quad . \quad . \quad . \quad (2)$$

From this we have

$$\mathbf{s}.\mathbf{s} = (\mathbf{r} + \lambda\mathbf{m}).(\mathbf{r} + \lambda\mathbf{m})$$

or

$$2\mathbf{r}.\mathbf{m} + \lambda\mathbf{m}.\mathbf{m} = 0 \quad . \quad . \quad . \quad (3)$$

the equation that gives the wave-length.

The directions of the incident and emergent rays make the same angle with the vector $\mathbf{m}$ and this might be called the incident angle. The glancing angle θ, which it is the custom to measure, is the complement of the incident angle, and is the angle made with the mesh planes perpendicular to $\mathbf{m}$. It is given by

$$\cos 2\theta = \mathbf{r}.\mathbf{s}$$

which by the help of equations 2 and 3 becomes

$$\sin\theta = \frac{\lambda}{2} \text{ times the magnitude of vector } \mathbf{m}.$$

When m_1 m_2 m_3 are prime to one another, the distance d between successive mesh planes is the reciprocal of the magnitude of $\mathbf{m}$, so that

$$\sin\theta = \frac{\lambda}{2d}$$

The derived reference frame is equally appropriate in three dimensions and in four. D. B. MAIR.

Weather Prediction from Observation of Cloudlets.

MR. CAVE writes: "I am not sure that I understand the second of Sir Archdall Reid's definitions of cloudlets—'small diaphanous clouds that can be seen at the same time in every part.'" The preceding definition was "the smallest and thinnest fragment of cloud that can be clearly isolated." I do not know how to express myself more plainly. On the other hand, Mr. Cave and I may not mean the same by "cumulus" and "cirro-cumulus." If there be any difference, then, since I am a mere amateur, I am sure he is right. I can only say that my suggestion as to the utility of observing cloudlets is founded on many years' experience, and, so far as I can judge, on common sense. To me it appears true (1) that rain is preceded by the condensing of clouds, and a return of fine weather by their dissolving; (2) that when clouds wax visibly rain is probable, and fine weather when they wane swiftly; (3) that, in proportion to their sizes and densities, the waxings or wanings of big clouds are difficult to observe; (4) that, in proportion to their smallness, thinness, and isolation, the behaviour of cloudlets is easy to observe; and (5) that the behaviour of cloudlets is usually an index of the behaviour of neighbouring clouds, and therefore of current atmospheric conditions. I find it hard to believe that clouds *commonly* change their behaviours so rapidly "that the method is scarcely of more use than the tossing of a coin."

It may be, as Mr. Cave says, that "Lenticular cirro-cumulus is composed of cloudlets that are born on the windward side and die on the leeward side of the cloud mass"; but, if so, the fact puzzles me. I can understand why a cloud should condense on the windward side of a cold mountain peak and dissolve to the leeward I can understand that a cloud may grow on its cold shadowed side while dissolving on its sunlit slopes—though, because of the difficulties of observation, I have never seen this phenomenon. But I cannot understand how wind can so affect cirro-cumuli that they grow to windward and dissolve to leeward. Are not these cloudlets *in* the wind (and therefore, in a sense, *out of it*) like plums in a pudding? This phenomenon also I have not seen: or at least have not connected with the wind. However, this is not a matter for the "likes of me" to theorise about. The fact remains that any one, at any time, on any day, when cloudlets can be isolated, may test, in a few seconds, the utility of weather prediction by means of cloudlets. I think, like Dr. J. W. S. Lockyer, he will find it useful. I wonder whether Dr. Lockyer can remember whether the rapid growth of his cloudlets usually presaged rain, and their dissolution fine weather? May I insist once more that I have only sought to indicate what seems to me an easily observed and exceptionally reliable weather sign?

G. ARCHDALL REID.

Rate of Growth of Fungus Rings.

MR. O. G. S. CRAWFORD'S letter in NATURE of December 26, page 938, concerning the age of fairy rings, seems to warrant a letter for publication in addition to a more detailed private letter.

Fairy rings have been objects of interest from very early times and are the subjects of myths in most civilised countries, and are not beneath the notice of writers from Shakespeare to Kipling. As diverse as the myths are the suggestions regarding their mode of formation, ranging from fairy feet to fiery dragons and from thunder to moles.

It is now common knowledge that the rings are the result of a perennating fungus-mycelium and not of an annual spore discharge and germination. It is sometimes alleged that rings may remain stationary for several years; W. G. Smith stated that he knew a fairy ring of *Clitocybe geotropa* on Dunstable Downs which had remained much the same size for forty or more years. Most observers, however, agree that normally the rings increase in size. The rate at which the mycelium extends outwards varies considerably and is apparently dependent on weather conditions. There have been few actual measurements. Thomas studying rings of *Hydnum suaveolens* over a period of nine years found an average annual increase of 23 cm. Ballion records an increase of 12 cm. in one year for *Marasmius oreades*, but the advance was irregular being apparently more rapid when the ring was young, whereas for *Psalliota arvensis* the average increase was more than 50 cm. Bayliss with *Marasmius oreades* found the minimum annual increase to be 3 inches, the maximum 13½ inches. Shantz and Piemeisel estimated the average yearly advance as 12 cm. for *Agaricus tabularis*, and calculated certain Californian rings to be about 250 years old, and a number of small fragmentary rings which apparently had a common origin as approximately 600 years: the largest ring of *Calvatia cyathiformis*, with an average annual increase of 24 cm., was more than 400 years old.

It is obvious that the rate of advance depends upon the species of fungus concerned, and also upon conditions of environment which necessitates observations over a number of years.

It may be remarked that Prof. Buckman mentioned rings on Salisbury Plain more than fifty feet in diameter.

On the Structure of the D_3 Line of Helium.

DUE to the position of helium in the periodic table, relative to that of the alkaline earth metals, it has been frequently pointed out that its spectrum should consist of systems of singlets and triplets instead of the observed singlets and doublets. An unsuccessful attempt has been made to resolve the strong component of the doublet into the two expected components with the expected separation of approximately 0·17 Å.U., since the separation of the observed components is 0·34 Å.U. approximately.

A helium discharge tube wrapped in cotton which was kept wet with liquid air was used as a source, and the light was resolved by means of a quartz Lummer Gehrke plate and a small quartz spectrograph. Fortunately, the dimensions of the plate were such that one order fringe of the main component almost coincided with the next order fringe of the observed component. These together produced a single fringe of width about 1/5 the total distance between the fringes. The component looked for under these conditions should occur half-way between fringes.

Careful examination of the fringe system by both of us failed to reveal any trace of the expected component, though it would have been observed had ts intensity been equal to or greater than 1/40 that of the main component of this line and its separation rom the main component greater than 0·08 Å.U. Thus it appears that the structure of the $(1\pi - m\delta)$ series of helium does not correspond to the equivalent eries of the alkaline earth metals, calcium, etc.

A Possible Origin of Petrol-Fields.

IT has frequently been suggested that natural mineral oils may be the product of decomposed fish. One of the main objections to this explanation has lways seemed the difficulty of accounting for the oncentration of oil deposits within the comparatively restricted areas in which they actually occur. But if one considers the migration of certain fish, for example he common eel, this objection can, in the main, be vercome.

It has now been definitely established that all the European eels make their way to a certain deep-sea rea in mid-Atlantic, where they spawn. The mature eels do not seem to return after spawning, only their ffspring appearing in the rivers in due course in vast numbers. If, as is probable, they die after reproduction, there must be enormous deposits under their pawning grounds, which might eventually be in part onverted into oil.

The quantities involved in this hypothesis appear o be in no way unreasonable. If one allows a eriod of say 10^7 years for the formation of the nited States oil-fields, which are estimated to have ontained two to three thousand million tons of oil, nd if one assumes that one eel on an average would rovide 100 gm. of oil, then to account for these eposits one would have to postulate an annual migration to the spawning ground of only 2 to 3 million eels. Thus even if the time and the yield have been overestimated by a factor of 10, there would still be a comfortable margin.

Measurement of Radiation Intensities by Photographic Methods.

REFERRING to Dr. F. C. Toy's letter, under the above heading, in NATURE of January 16, p. 83, Dr. John S. Anderson and I came to the same conclusion in an investigation published in the *Proc. Roy. Soc. Edin.* fourteen years ago. In the words of this paper, "Only when two beams of light of the same wave-length fall on adjacent parts of the same photographic plate and produce equal blackening in the same time can we say that their intensity is equal." This principle was made the basis of all the work we did at that time on ultra-violet spectrophotometry. But there are some fields, such as astrophysics, where it cannot be applied.

The object of this letter is to direct attention to the simple method we used for cutting down the intensity of the stronger beam. Half the slit of the collimator was illuminated by the light of an iron arc, and in the line between the slit and the arc travelled a ground quartz diffusing screen. The rays from the quartz screen filled the whole object-glass of the collimator. The intensity of illumination of the half slit varied consequently as the intensity of illumination of the ground quartz, and the latter varied inversely as the square of its distance from the arc. I have since used intermittent sectors and "neutral" absorbing screens which Dr. F. C. Toy favours, but am still of the opinion that for reducing the strength of the beam the inverse square law is preferable.

The Occurrence of Dwi-Manganese in Manganese Salts.

FROM our respective communications (NATURE, vol. 116, p. 782; *Chem. News*, vol. 131, p. 273, etc., 1925) it was apparent that, although working on different lines, we had detected the element of At. No. 75 in manganese salts. A sample brought by one of us to Prague has been examined in the laboratories of the Charles' University. The sample was obtained from a solution of "pure manganese sulphate" by removing as much manganese as possible with hydrogen sulphide. When examined polarographically and also spectroscopically, it showed a similar content of dwi-manganese, namely, one per cent. The chemical properties of this mixture agreed with those previously announced from this University. Since we have reached the same conclusion by independent chemical and electrochemical methods, we consider the association of dwi-manganese with manganese as proved, and thus regard the name dwi-manganese (D) as most appropriate for the element At. No. 75.

The Advancement of Engineering in Relation to the Advancement of Science.[1]

By Prof. A. E. KENNELLY, Harvard University.

THE term engineering is employed with many different shades of meaning. Tredgold's famous definition of civil engineering, which appears in the charter of the Institution of Civil Engineers (London), dating from 1828, commences with the excellent phrase "—the art of directing the great sources of power in nature for the use and convenience of man—." In Tredgold's time there were only two recognised types of engineering—*i.e.* civil and military. At the present time, nearly forty different branches of engineering have been itemised in technical literature. For the purposes of this discussion the following broad definition is suggested to cover all types of non-military engineering: "the economic application of the sciences to construction, production or useful accomplishment, especially on a large scale."

From this point of view, engineering manifests itself as the activating principle in the industrial world. Engineering, in this sense, must not only be coeval in antiquity with civilisation; but the degree of engineering attainment in any age must also necessarily be an index or criterion of its civilisation, judged from the material aspect.

The present era, which is essentially an engineering age, may be said to date from the introduction of the steam engine, and in that sense is only about one hundred years old. The application of the science of heat, in relation to steam for generating power, rapidly changed the nature of production from the individual-worker system to the factory system, augmenting greatly the output of a day's work. This in turn brought new dense factory populations, and also brought the means of supporting them. The so-called industrial revolution, thus started, brought tremendous sociological changes in its wake. Rapid steam transportation accelerated commerce and developed markets. It enabled producers to find sales for their products over a continually enlarged area. A sense of economic emancipation dawned over mankind.

During the Middle Ages and the Renaissance the study of science was slowly advancing in the western world, mainly under the guidance of the universities. This study consecutively followed the growth of mathematics, and was seldom directed to engineering applications. The natural philosophers, chemists and mathematicians who lived in the early years of the nineteenth century, taught and worked in intellectual regions usually remote from applications to utility. The rapid growth of the steam engine for driving factory machines, in the early years of the engineering era, brought into existence the mechanical engineer, who received his training in the workshop and factory. The mechanical engineer was compelled to study the nature of heat engines and of combustion, the laws of mechanics, and the properties of machines. This scientific study was, at first, more or less empirical and unsystematic. In the early days of mechanical engineering the physicists and scientists were ordinarily so far removed in their experiences from machines and engineering that they saw no way of co-operating with the engineer; while the engineer was so completely engrossed with the practical details of his work that he could see no way of receiving help from theoretical science.

The last few decades have steadily drawn together these two types of men and schools of thought, by mutual modification. The constantly increasing scale of machinery and machine production has necessitated more concentrated scientific study of the principles involved. The engineering applications have demanded more scientific knowledge, and the scientists have become more interested in applications. Until about fifty years ago the initial training of a young engineer, after leaving school, was either by apprenticeship to an engineering workshop, or by being articled, as an assistant, to a practising engineer. It is now recognised that the best training is in an engineering school of a university or technical college, where special study i devoted to the fundamental arts and sciences, followe by technical or applied science in some particula branch.

It is not only in the particular fields of engineerin that this close dependence of application upon th sciences has become essential; but also in manufacturing and general production. It may be safel asserted that manufacture, on a large scale, is so closel associated with engineering processes as virtually t become engineering itself. In other words, in order t carry on manufacture economically, on a large scale the process is practically the same as engineering There is the same need for scientific study of th principles and basic materials involved, the same nee for careful and thorough design, with the view o eliminating waste in material, plant or labour, the sam need for experience and skill in the various stages of th work, and the same necessity for careful preliminar estimates of cost, as well as of checking the cost i successive stages.

Every labour-saving appliance in manufacture, an every scientific improvement introduced into its procedure, is a new evidence of the identity betwee modern manufacture and engineering. A manufacturing community, in modern times of competiti and development, is of necessity an engineerin community.

Prior to the amalgamation of science and industry our present engineering age, the advancement of scien was made mainly in places where science was studi and taught; *i.e.* in universities, or institutions scientific learning associated therewith. Since t amalgamation, however, an increasing share in t advancement of science has been carried on in enginee ing establishments; *i.e.* in industrial laboratories, factory laboratories, or in government and sta laboratories. In future, the advances of engineerin and of the sciences upon which engineering depend will be so bound up and interconnected that whatev gives one a step forward must also give a like impu to the other.

It would no longer be possible to maintain the hu populations of many large cities in the world without engineering; *i.e.* without the continued economic application of the sciences to the supply of the many products those cities require.

---

[1] From the address of the retiring chairman delivered on December 30, 1925, before Section M (Engineering), at the Kansas City meeting of the American Association for the Advancement of Science.

Although the needs of utility have in recent years either suggested or demanded numerous scientific researches, it is manifest that many other researches in the sciences are and will doubtless continue to be made exclusively for the truth's sake, and independently of any specific utilitarian need. It is only necessary to consider any scientific subject in all its bearings, to realise that this must be so. The great science of mathematics, for example, must evidently be greater than the sum of all its applications; so that unless all scientific curiosity as to the nature of new mathematical relations shall disappear, many investigations must continue to be made into branches of the subject that appear to have no immediate applications. Moreover, many cases of scientific research which have been made without any suspicion of applicability have afterwards come to be applied to very practical use. It would seem that the only differences which necessarily separate a scientific research of the basic or non-applied type, from one of the applied type, lie in the aims and motives of the researcher. In other words, one and the same research, conducted in the same way, may be an applied-science research or a basic-science research, according only to the purpose in the mind of the person who carries on the work.

It is generally conceded that researches carried on for the advancement of science tend strongly to stimulate the imagination. The investigator is called upon, at every stage of experimental inquiry, to speculate upon all the possibilities that present themselves, and to set up a new test that may serve to demonstrate which are the actualities and which the unrealities. It is not so generally recognised, however, that the work of the designing engineer also makes special claim upon his maginative powers in the material realm. Any new project, such as a large bridge, building, railroad or power plant, calls for a careful estimate and design. t has to be completely visualised, part by part, in the mind of the designer, before construction commences. The designer has then, either alone or with the aid of assistants, to realise his plans in two-dimensional drawings. A large project may involve the preparation of many hundreds of drawings, in advance of assembling the materials. All of these drawings must nterlock and connect in technique and dimensions. Tracings and blueprints from these drawings are then provided for guiding the constructors in their various asks. The assemblage of design drawings embodies in most new undertakings a considerable amount of nvention, imagination and creative work, which the builders proceed to translate from small scales in two dimensions, to full-size three-dimensional reality. To the trained eye, a good construction blueprint reveals, under its network of lines, a wonderful image of eality.

In the engineering of building construction, provision made for the proper conservation of æsthetic grace, y the profession of architecture. On its artistic side, rchitecture seeks to foster and promote the art of beautiful building construction. This professional attitude towards art in the engineering of buildings guides public opinion in such a way that graceless and inharmonious buildings seldom escape popular censure. In other branches of engineering the æsthetic quality of the product does not at present find similar professional safeguard. Nevertheless, there is, for each type of engineering construction, a certain somewhat indefinite standard of artistic appearance below which the designers and builders are sure to encounter hostile criticism. In every country, new types of machines, which are experimental and have not yet established their right to survive, are usually revealed by their awkward appearance. Each country develops, as a general rule, its own type of æsthetic standards in appearance, and experts frequently detect, in this way, the nationality of machines and the relative artistic engineering excellence of the nations in which those machines were produced. It is here again that the advancement of science reacts upon advancement in engineering; because the harmony in Nature that scientific study discloses, tends to guide the minds of those who apply the great principles of Nature to the satisfaction of human needs.

Just as the advancement of engineering construction, as for example in telescopes, is constantly tending to the advancement of the sciences, or of astronomy in the case considered; so in return the advancement of science is constantly tending to the advancement of engineering processes. Thus, the precision of geodetic surveying has greatly increased during the last few decades, owing to progress in the sciences of astronomy, mathematics, physics, metallurgy, geology, and others. Moreover, the demands made upon engineering design and construction tend ever to become more exacting. For example, it has recently been stated that the great new Philadelphia-Camden bridge across the river Delaware is the first in which the supporting towers have had to be given extra strength to withstand the possible accidental impact of an aeroplane.

So close is the present interconnexion between science and engineering that the only salient distinction between them lies in their respective relations to economics. Questions of cost inevitably present themselves in the study of basic scientific problems, if only as limitations to equipment; but they are ever present in the study of engineering problems. Indeed, engineering problems call for special methods of accounting, and emphasise the importance of determining amortisation, depreciation, effective rates of interest and present values of plants. The stocktakings of large-scale businesses likewise tend to become both economic and engineering inquiries.

As the entire civilised world becomes more and more given over to engineering, if only in order to support its large populations, it becomes evident that the conversion of factories for producing utilities into agencies for developing destructive and poverty-making warlike implements, is ever easier. The power of science to create in the hands of those who help, becomes equally the power to destroy in the hands of those who fight. The world has only too recently seen how terribly destructive the powers of science and engineering can become in war among the industrialised nations. Modern war is engineering gone mad. This misuse is, of course, no fault of either science or engineering. If, however, in the reasonably probable advance of both, we are to avoid the utter destruction of civilisation by war, and the economic servitude of posterity in its wake, we must all unite in building an international organisation that shall not only tend to prevent the onset of war but shall also swiftly suppress its first outbreaks. In any such organisation, both science and engineering are sure to be powerful elements for effecting control. Under such control, once successfully established, the advancement of science and engineering should surely promote and maintain world peace. Even now all science and its applications are essentially international. No way has ever been found to make science operate exclusively for the benefit of one nation, or portion of the globe.

In the basic sciences, the units of measure employed are almost universally the simple units of the international metric system—the metre and the gram—with their derivatives. In engineering and applied science, the units employed have gradually likewise become metric in all parts of the world except in the English-speaking countries, where both the time-honoured but cumbersome English and American systems of units persist. Even in the English-speaking countries, however, a gradual transition may be perceived towards the ultimately inevitable international metric system. When the transition shall have become complete, the mutual advances in engineering and in science will be rendered more easy and rapid, through the use of the same language of units. This simplification will benefit science and engineering in all parts of the world.

The advances of science and of engineering have thus far always enriched mankind materially. Material production has been greatly hastened; so that the average possessions of men have been increased, or else larger populations have been supported to divide the increase. It is doubtful, however, whether increase of human happiness, beyond a relatively small modicum of possessions, is at all commensurate either with the growth of material wealth or with the growth of population. It seems that while science can largely increase general comfort and prosperity, it can, at present, ensure but little increase of happiness and contentment. Whether this must always and inevitably be so, is debatable, and depends to some extent on our definitions of science. In any case we must turn for help to moral and spiritual sources of happiness if we are to continue to become increasingly indebted for material wealth to the scientific revelations of the interpretable universe. At present it appears that advancement in the power to enjoy and give contentment is more difficult for us collectively to acquire than advancement in the power to secure material benefit through science and engineering. In the discovery and maintenance of these uplifting philosophies the calm and contemplative Orient has surpassed the tense and restless Occident.

It is generally admitted that the study, either of the sciences or their applications, tends to produce in the mind of the student a sense of humility and a respect for truth. Indeed, it is not strange that habits of seeking or applying scientific truths should engender habits of faithful thinking. In this respect there is encouragement in the belief that the tendency of the present engineering age is, on the whole, towards accuracy of reasoning and precision of thought. Scientific ideas may tend slowly to dominate over irrational and irregular thinking. A casual review of general literature over long periods of time seems to show that as science has advanced, irrational and superstitious ideas have dwindled. The concomitant danger, however, lies in the occasional ravages of erroneous pseudo-scientific doctrines. A plausible but false doctrine, that masquerades as a scientific proposition, may produce more harm in a scientifically disposed world than a flagrantly immoral popular belief of a clearly irrational character. The responsibility for making unguarded statements that are unsupported scientifically, thus rests increasingly upon all speakers and writers.

In the development of the applied sciences, a constantly increasing demand devolves upon the underlying basic sciences. In the prehistoric times of primitive engineering, only the simple rudiments of the underlying sciences may have been involved. In the ancient Egyptian and Roman days, engineering must have demanded a closer study of mathematics and physics for support. Since, however, the dawn of the present engineering age, much more knowledge and research have been demanded in a long list of the branches of basic science. Invention is always needed. But whereas in past times, inventors, if they had the requisite talents, did not need much scientific knowledge, at the present time the successful inventor has not only to be endowed with inventive ability, but he must also be well versed in basic science. It appears that in the future this demand for basic scientific knowledge, as a prerequisite to applied-science progress, will continually increase.

The leadership of the ancient world rested mainly upon physical force. The trend of the more recent past through the present, towards the future, is for world leadership among the nations to rest mainly upon science and its applications. Already the progress of engineering is hampered and thwarted in many directions by lack of advance in the basic sciences. It is to these that national attention should be directed for the progress of the knowledge that benefits first the nation in which it is made, and later all the other nations. If only in the interests of applied science, the advancement of basic science should be stimulated and fostered. Support for applied science is likely to be forthcoming from the industries themselves; but support for basic science is more difficult to secure.

The national importance of this is so great that the need should be made widely known. An effective way to stimulate advance in the sciences in the United States would be to secure permanent endowment for a suitable annual prize, to the most notable contribution each year, in each section of the American Association for the Advancement of Science. This official recognition of scientific achievement would stimulate and encourage researchers in all the sections. There is no reason to fear that such scientific progress might be practically valueless. Useless scientific knowledge is now a contradiction in terms. Moreover, aside from the question of immediate versus future application, the patient earnest study of truth, in those parts of the universe that are attainable to us mortals, constitutes the noblest quest with which we are yet acquainted.

The Production of Motor Spirit from Heavy Oils.

By Dr. A. E. DUNSTAN.

IT is obvious that the provision of adequate supplies of motor fuel is a fundamental necessity of modern civilisation. Thirty years ago the light fractions of petroleum were not only a by-product in the preparation of kerosene, but also a positive nuisance, and vast quantities were deliberately burnt. In the interim the demand for motor spirit has steadily increased, and to-day has reached the colossal figure of eleven thousand million gallons per annum, Great Britain consuming nearly four hundred and fifty million gallons in the year.

This demand is increasing at the rate of about 30 per cent. a year in Britain alone, whilst the rate of increase on the Continent when trade becomes prosperous will inevitably be steeper than that in England. Last year, of the total amount of petrol produced in the United States, the straight-run gasoline distilled from the crude amounted to 56 per cent., cracked gasoline 33 per cent., natural gas or casing-head gasoline 10 per cent., and benzene 1 per cent.

It is clear that "cracking," *i.e.* the conversion of heavy oil into lighter products, is playing a more and more important part in the provision of motor spirit. The first successful attempts to bring about the conversion of heavy oils into lighter products were achieved by Dewar and Redwood in 1889 (English Patent 10277), and the object of this operation was the conversion of gas oil into burning oil. It was many years later that the conversion of burning oil and gas oil into petrol became desirable and practicable.

Although Redwood's patent was taken out in 1889, the writer had the advantage of seeing some time ago in Edinburgh a lay-out of a shale oil refinery in which this operation was actually provided for so far back as 1865.

The actual origin of cracking in the United States is supposed to be due to the carelessness of a stillman who, having left a still running, returned some hours later and found that a lighter distillate was being produced, and this was traced to condensate dripping from the upper cooler part of the still on to the hot residue. Between this early discovery and present-day big-scale cracking lies a period of intensive development, and it was only the perseverance of Dr. Burton that led to a refinery procedure being established on a large scale. The Burton process is really indistinguishable from that put forward by Dewar and Redwood; in effect, Burton merely heated petroleum residues at a temperature of 700° F. under a pressure of 4-5 atmospheres, the pressure being maintained right up to the outlet of the condenser. The real difference lies in the fact that Burton had developed the same procedure, but to a different end—the production of gasoline.

The first Burton patent was taken out in 1912. For a long time the Burton process was regarded with some disfavour, because of the relatively high pressure maintained in the still and the somewhat serious risks incurred by heating large masses of oil under these conditions, and the attention of innumerable investigators was directed to the cracking of hydrocarbons under atmospheric pressure. In Great Britain, for example, about the years 1913 to 1916, two at least of such processes were in operation. They failed, however, because the serious drawback of low pressure operation is a high yield of gas with corresponding low yield of gasoline, and that of a nature which makes refining extremely difficult. As will be seen in the sequel, it is by no means certain that vapour-phase cracking at atmospheric temperature is entirely defunct, because the nature of the spirit produced does offer certain advantages as a fuel for modern high-compression engines.

During the War, quite a considerable amount of attention was paid to vapour-phase cracking from an entirely different point of view. It has long been known that at temperatures in the neighbourhood of 750° C., paraffinoid hydrocarbons may be cracked, yielding considerable percentages of aromatic hydrocarbons. In a large-scale experimental plant operated at Thameshaven in 1916, working with heavy Persian oil distillates, a spirit was produced which contained no less than 16 per cent. of toluene.

Between 1916 and the last few years, however, the attention of inventors has been almost entirely directed to cracking under pressure, because it has been found that the spirit produced in this way is not only higher in yield but is also accompanied by far less gas and coke.

One or two typical methods of procedure may be very briefly outlined. In essence, all these processes consist of two parts: A pipe-still through which the oil is passed with considerable velocity at high temperature and pressure into a reaction vessel, in which it is maintained under pressure for varying lengths of time.

In the Cross apparatus—which is one of the most popular types—the oil is raised in the pipe-still to a temperature of about 470° C. and then passes into a reactor, which consists of a horizontal steel cylinder 40 ft. long, 38 in. in diameter, with walls 3 in. thick. The reactor is not directly heated, but is heavily lagged, and the oil is held in this chamber long enough to establish equilibrium between the liquid and vapour phases. This period is about 15-20 minutes, and the oil falls in temperature 50° between the inlet and the outlet. The operating pressure may amount to 750 lb. to the square inch. Normally in this process the amount of coke produced is less than 1 per cent.

After the reaction is complete, the oil is discharged into a separator and thence the vapours pass to the dephlegmator, where the temperature is regulated to yield gasoline to the required specification. The gas that is produced is nearly sufficient to maintain the necessary temperature in the plant. A modern unit will process 2000 barrels of oil per day, and if the intermediate oils produced in the operation be recycled to the plant, it is claimed that the yield of gasoline from a gas oil fraction may reach 65 per cent.

The Carleton-Ellis developments have led to the adoption of a vertical reactor which may be in duplicate. Oil is fed through the pipe-still under a pressure of 350 lb. and passes into vertical steel vessels, in which again the time factor is allowed to have its effect. After the reactor comes the dephlegmator.

The Dubbs' system is particularly adapted to the cracking of residue oils, although of course it will function on distillates. The process is simple in that the oil, after leaving the pipe-still, passes into a large reactor under a much lower pressure than that used by the Cross system. In the standard plant the oil enters the reaction chamber at 450° C., and the vessel is 10 ft. in diameter and may reach 30 ft. in height, with a capacity for coke ranging from 30 tons upwards. From the reactor again the vapours are subjected to dephlegmation, and a heavy condensate can be passed along with the incoming crude oil to the pipe-still.

The question of temperature in liquid-phase cracking is decided by the particular oil under treatment and the amount of gasoline required, because there appears to be a definite relationship between the variables time, temperature, and yield. It is interesting to note that the percentage of spirit obtained, after the oil has reached a definite cracking temperature, appears to double, within limits, for an increase of 10° C.

There has been little advance in our knowledge of cracking from a chemical point of view during the past ten years, because problems connected with cracking processes have been more often of an engineering nature, and the most urgent question to the majority of operators is the possibility of elimination—or at any rate the diminution—of coke, so that the plant may run continuously without the necessity for frequent shut-downs for cleaning.

It is surprising how little progress has been made in the examination of the residues left after the cracked gasoline has been removed from the synthetic crude oil, and investigators would do well to bear in mind that herein lies reactive material of unknown constitution, knowledge of which would probably amply repay intensive research.

Recent development in the design of the high speed, high compression, and high efficiency light car engine has brought to notice the importance of suitable fuel. It is in this connexion that cracked spirit shows particular advantages over straight run gasoline, in that it withstands high compression and is less prone to detonation, and it is a fact that, at the moment, quite considerable quantities of this material are being marketed as "anti-knock" motor spirit. The vapour phase product, having been processed at considerably higher temperatures, is specially noteworthy from this point of view.

No account of the present position of oil-cracking to-day would be complete without some consideration of the Bergius process, about which such far-reaching claims have been made. From the early work of Bergius there emerged the formation of artificial coal from cellulose at temperatures of 350° C. and pressures of more than 100 atmospheres. This substance was capable of hydrogenation by being heated to 400° C. in the presence of hydrogen at very high pressures. From this observation naturally led the application of hydrogenation to coal itself.

An entirely new technique had to be developed in this research and its later development, and only the discovery of a new method of joint construction rendered possible the application of very high pressures to this problem.

A commercial plant has been set up at Rheinau, and consists of an autoclave 30 ft. long × 3 ft. in diameter, fitted with stirring device and capable of handling 50 tons of material a day, under a pressure which may reach nearly 300 atmospheres.

In the case of coal, the material is ground to pass a 400-mesh sieve and is mixed with oil to permit of its passage through pipes. The autoclave is heated very ingeniously by surrounding it with heated nitrogen under pressure. Bergius has claimed that any coal containing less than 84 per cent. of carbon on an ash-free basis can be successfully hydrogenated.

In this connexion a good deal of work has been carried out the last few years in Great Britain, more particularly in the University of Birmingham, which more or less substantiates claims advanced by Bergius, and a variety of coals, lignites, and so on have been liquefied; but it should be borne in mind that the liquid product, whatever it may be, is certainly not petroleum, seeing that it contains liquid compounds of oxygen, sulphur, and nitrogen; and at the moment of writing it can be safely stated that the process has not yet been placed on a commercial basis.

Obituary.

Prof. Edmund Knecht.

By the death of Prof. Edmund Knecht, associate-professor of technological chemistry in the College of Technology, University of Manchester, chemistry, as applied to dyeing and other branches of textile industry, has lost one of its chief exponents.

Henry Edmund Knecht was the third son of Gustave Knecht, B.Sc. (Lond.), a Swiss who became a naturalised Englishman and for many years had a large private school in Liverpool, where Dr. Knecht was born in 1861. His mother was English. On leaving school he matriculated at the University of Zürich, studying chemistry under Victor Mayer, to whom later he acted as assistant. He graduated Ph.D. at the Swiss Federal Polytechnic in 1882, and returned to England in 1883 on his appointment as Head of the Department of Chemistry and Dyeing of the then newly opened Bradford Technical College. In 1890 he entered upon the long period of service at the Manchester College of Technology which ended only with his death.

When the Society of Dyers and Colourists was formed in 1884, Dr. Knecht became the first editor of the journal of the Society, a position which he held continuously for forty-one years and was the source of great satisfaction to him. To commemorate the completion of the fortieth year of his editorship, an excellent portrait of Dr. Knecht was issued with the journal and a valuable presentation was made to him, towards which subscriptions were received from the United States, Canada, India, Japan, and most European countries—for he had friends and admirers the world over.

Dr. Knecht was an indefatigable and prolific worker, his published researches, which number more than one hundred, appearing in the *Journal of the Society of Dyers and Colourists*, the *Journal of the Chemical Society*, the *Berichte*, and elsewhere. They cover a wide range, dealing with the production and application of dyestuffs, the chemistry of textile fibres and textile processes, etc. He also developed an entirely new series of analytical processes based on the use of titanium salts. He was the author alone or in collaboration of several standard works on dyeing, printing, and allied industries, the best known being the "Manual of Dyeing" by Knecht, Rawson, and Loewenthal. He also contributed a number of articles to the last edition of the "Encyclopædia Britannica."

Dr. Knecht was in good health until July last, when he underwent a serious operation from which he made a good recovery. Going to Switzerland to recuperate, he remained there until November, but during the whole time kept in close touch with the investigations carried on by his assistants in Manchester. Arriving in England during one of the worst fogs experienced for years, he caught a chill which developed into bronchitis, and he succumbed quite suddenly to heart failure on December 8 last, at his home at Marple, Cheshire.

As a teacher Prof. Knecht acquired a great reputation, not mainly through formal lecturing but by personal contact and example in the laboratory. The letters received from past students in many parts of the world at the time of the presentation recently made to him indicate the abiding affection in which many of them held "the Doctor."

Dr. Knecht was never married, but is survived by three sisters. He had the gifts of humour and good comradeship, but to hide an excessive sensitiveness and shyness he had also a natural reticence which was penetrated only by his intimate friends. His publications are characterised by sound judgment and lucidity, and frequently by those flashes of vision which connote genius. To no other man does the Society of Dyers and Colourists so largely owe its present considerable reputation; and it may truly be said that no man in any country has done more to enrich our scientific knowledge of textile materials and processes.

WALTER M. GARDNER.

MR. R. B. NEWTON, I.S.O.

RICHARD BULLEN NEWTON, lately senior assistant in the Geological Department of the British Museum, was born in London on February 23, 1854. His father was Librarian and his uncle (Mr. E. T. Newton, F.R.S.) Palæontologist to the Geological Survey. He was educated at the Central London Foundation School, Cowper Street, entering there as one of the first scholars. At the age of thirteen years, Newton obtained work at the Geological Survey, and in 1873 became one of the assistant naturalists under Huxley. In 1880 he was transferred to the British Museum and was soon engaged in the removal of the geological collections from Bloomsbury, and the rearrangement in their new home at South Kensington. He became an expert conchologist and especially interested himself in the Tertiary Mollusca, issuing a systematic list of the Edwards Collection in 1891. Other contributions flowed from his pen, to the number of about a hundred; many of them, though professedly systematic reports on collections of fossils sent to the Museum from distant regions, constituted considerable additions to our geological knowledge of Africa, Asia, and the near East. Another branch of his work was the study of the Foraminifera as guides to geological horizons.

In 1914 Mr. Newton received the Wollaston Fund from the Geological Society of London. He was president of the Malacological (1910–12) and of the Conchological Society (1913–15). His wide knowledge of fossils and their literature and his familiarity with the national collection made his services of much value to the British Museum and to the Empire at large. Since his retirement from the service he had continued to work in his old room at the Museum, and was hard at work there until, only a few days since, he left to undergo the operation to the effects of which he succumbed on January 23, in his seventy-second year. His helpful presence will be greatly missed by all his colleagues.

F. A. B.

WE regret to announce the death of Dr. Karl Goldschmidt, chairman of the directors and for many years head of the executive of the firm of Th. Goldschmidt and Co., of Essen, who succumbed to an operation on January 5 at Stuttgart, at the age of sixty-eight. He and his brother, the late Prof. Hans Goldschmidt, were well known as the inventors of "thermit," and in a recent monograph entitled "Aluminothermie," Karl Goldschmidt has described fully the nature and importance of the thermit-reaction. The brothers inherited from their father a chemical manufacturing business, which they transferred from Berlin to Essen thirty-five years ago. Under the management of Karl Goldschmidt, the business developed enormously and in 1911 it became a public company.

WE regret to announce the following deaths:

Dr. Charles A. Doremus, formerly professor of chemistry and toxicology at the University of Buffalo, known for his work on foods and on the chemistry of sanitation, on December 2, aged seventy-four years.

Mr. C. M. Doughty, honorary fellow of Gonville and Caius College, Cambridge, traveller and poet, the author of "Travels in Arabia Deserta," on January 21, aged eighty-two years.

Dr. C. Iris Fox, senior assistant pathologist at the Royal Free Hospital, Gray's Inn Road, London, who died as the result of a poisoned finger sustained during a *post-mortem* examination, on January 21.

Prof. C. Golgi, emeritus professor in the University of Pavia, Nobel prizeman in medicine with Prof. Ramon y Cajal in 1906, and distinguished for his work on the histology of the nervous system, on January 21.

Prof. H. A. Gossard, chief of the Department of Entomology of the Ohio Agricultural Experiment Station and president of the American Association of Economic Entomologists, on December 18, aged fifty-seven years.

Dr. W. R. Lang, formerly professor of chemistry in the University of Toronto, known for his work on low-temperature phenomena and on the chemical industries of Canada, on November 20.

Prof. Edward S. Morse, formerly professor of comparative anatomy at Bowdoin College, and also of zoology at Tokyo, an authority on Mollusca and on Japanese ceramics, who was president in 1886 of the American Association for the Advancement of Science, aged eighty-seven years.

News and Views.

An interesting announcement was made by Lord Reading in his speech as Viceroy at the opening of the Indian Legislature on January 20. A Royal Commission is about to be appointed: "generally to examine and report on the present conditions of agricultural and rural economy in British India." There follow particular directions, of which one is glad to see that the first subject of investigation will be "the measures now being taken for the promotion of agricultural and veterinary research." From time to time we have had occasion to direct attention to the remarkable success—particularly in plant-breeding—that has followed the labours of research workers at Pusa and other centres in India. There can be little doubt that the economic results that have already been achieved will impress the Commission, and that, as a result, a further extension of the work will be recommended. We hope the Commission will pursue the matter to the conclusion which the experience of state-directed research in Great Britain suggests, namely, that the successful exploitation of scientific research rests, in the last analysis, on fostering the supply of scientific workers. Considering the subject of economic botany alone, it is a somewhat remarkable fact that—save in some degree in the University of London—no universities in Great Britain undertake the specialised training of botanists in the economic aspects of the science. For some years past there has been a strong demand from India and the Dominions for trained geneticists, mycologists, and entomologists. It is not suggested that it would be possible to train men in England in the specific applications of these subjects in foreign countries, but training in the principles of the economic application of such sciences as genetics might well be attempted. As a corollary to this proposition, the new Commission might perhaps consider the desirability of assisting the universities by means of scholarship grants, or otherwise, following the time-honoured precedent of recruitment for the Indian Civil Service.

Presumably the Secretary of State for the Colonies will soon proceed to the appointment of a Director of the Amani Institute in Tanganyika. On December 9 the announcement was made in the Kenya Legislative Council that following on the recommendation of the East Africa Parliamentary Commission, the Secretary of State for the Colonies was taking steps for the re-establishment of this Institute. Each of the East African territories was asked to make a contribution towards its maintenance, their total contributions amounting to 8000*l.* yearly. In addition, initial capital expenditure of 6000*l.* was to be incurred. The contribution of the Imperial Government had not then been determined but it was hoped a sum would be set aside from the 10,000,000*l.* development loan. This announcement was received with enthusiasm by the representative of the Kenya settlers, Lord Delamere, who stated that the Colony stood to gain advantages out of all proportion to the contribution of 1200*l.* for which it was asked to make provision. But as the *East African Standard* pertinently remarks, the selection of the staff will need to be made carefully. It is obvious that the Director should be an able administrator and one who can command the confidence and continued support of the Governors, the Directors of Agriculture, the settlers, and the leading traders—preferably one who has a knowledge of the varied elements of the population and its needs For upon his relations with the various administrative and executive elements in the territories and his knowledge of the conditions prevailing will the success of this experiment depend. Perhaps these qualities can be found in one who could bring also a specialist's experience to bear upon the scientific problems with which the Institute is to deal. But the other desiderata should be the determining factors in the choice of a Director who will secure for the Institute the confidence and support necessary for its success.

The two children's lectures under the Dr. Mann Trust at the Royal Society of Arts this year assumed a strikingly novel form in the hands of Prof. H. E. Armstrong. They were, in fact, not lectures at all in the conventional sense. Prof. Armstrong conceived the characteristically original plan of imparting a notion of scientific method and its application to some simple things of daily life by going back to Lewis Carroll and the immortal Alice, and the lectures were entitled "Alice in Wonderland at the Breakfast Table." The plan was that a team of children assuming the familiar characters and acting under the general direction and commentary of Prof. Armstrong as a sort of Sage, should work out an experimental elucidation of some questions centring round carbon. Beginning with sugar and an excursion into the realm of nutrition, the course ended with the chemistry of egg-shell substance. The experimental procedure was masked, so far as possible, by breakfast-table appliances and procedure on "Alice" lines, and excellent effects were obtained by the use of very simple properties.

It was evident that much thought and ingenuity had been bestowed by Prof. Armstrong upon the production, but there had been a singular spell of ill-luck, several important members of the caste having to fall out at a late stage owing to illness or quarantine. In these circumstances the presentation necessarily seemed somewhat unrehearsed. The experimental part was excellently conceived and executed. The Mad Hatter had fortunately maintained a clean bill of health and played his leading part quite admirably. He had upon him (perhaps unconsciously) the burden of being the grandson of the two men who, in their generation, did more than any of their contemporaries to make science-teachers consider their ways—Prof. Armstrong in the physical and the late Prof. Miall in the natural history sciences. Though the representation suffered from the troubles already referred to, and though the "book" and comments in some places seemed to be a little out of tune with the juvenile mind, the venture was of very remarkable originality and interest. It left some of the adult members of the audience with the feeling that if Prof. Armstrong were to take his troupe on a provincial tour, it might reappear in one of the little (chemical) theatres of London and even make a modest bid for favour at Christmas with "Peter Pan."

In his Friday evening discourse at the Royal Institution on January 22, Sir William Bragg dealt with "The Work of the Davy Faraday Research Laboratory." He said the Laboratory was founded in 1896 by the late Dr. Ludwig Mond, who provided building, equipment, furniture and an endowment for its upkeep. It was entrusted to the care of the managers of the Royal Institution. Its purpose was the development and extension of chemical and physical research by methods suggested in the deed of trust, or by any other means that appealed to those in charge of the Laboratory. It was to be open to workers of any nationality, the sole qualification being the ability to carry on research, and no fees or expenses for electricity, water or gas were to be charged. This was, indeed, a free and generous foundation. The laboratory is well adapted to team work, inasmuch as it provides room for some fifteen to twenty workers, who can conveniently exchange ideas and give mutual assistance. It is actually employed in this manner, and all its rooms are occupied. The main problem under attack is the application of the new X-ray methods to the study of organic substances, that is to say, such substances as are of main importance in living organisms, and such other substances as are of similar structure and composition. This covers a vast range of materials, fats, oils, paraffins, alcohols, dyes, explosives, and so on. The work done is in the main contained in the realm of pure science. The new methods of analysis by X-rays are continually showing promise of useful applications to many industrial problems, but it is desirable that such laboratories as the Davy Faraday and the university laboratories should not allow themselves to be drawn away too far from the problems of pure research. If the latter be neglected, industrial applications will in the end lose their vitality.

In the improvement of our roads and canals in pre-railway times none played a more important part than Thomas Telford, whose great bridge over the Menai Straits was one of the finest engineering feats of the time. The bridge was opened on January 30, 1826, by the passage of the London and Holyhead mail coach across it, and it has therefore been in use for just a century. Its central span is 580 feet, while the carriage way is carried at a height of 100 feet above the water way. Early iron suspension bridges were usually made of ordinary chains, but in the Menai Bridge, Telford formed his links of flat bar iron 1 inch thick, 3½ inches wide, and 10 feet long. There are sixteen chains in all and the total sectional area of the main chains is 260 square inches. The cost of the bridge was 120,000*l*. Telford was sixty-eight years of age when the bridge was opened, but he continued to practise his profession until almost the end of his life. He died at 4 Abington Street, Westminster, on September 2, 1834, and was buried in Westminster Abbey.

The official opening on Thursday last, January 21, by Lord Lloyd, of the Sennar Dam across the Blue Nile at Makwar in the Sudan, marks the completion of the first stage of a great enterprise by which, ultimately, something like 3,000,000 feddans (Egyptian acres) of hitherto barren land will be rendered cultivable. The full scheme contemplates the provision of two dams, the second being across the White Nile at Gebel Aulia, a short distance south of Khartum; this will be required to ensure the summer water needs of Egypt. The area immediately available for cultivation amounts to 300,000 feddans and lies in the valley of the Blue Nile below Wad el Haddad, to the west of Barakat, which is the headquarters of the Sudan Plantations Syndicate, where a cotton-ginning factory has been established. The Sennar Dam is 3025 metres in length, but only 1800 metres of this is dam, properly so called, the remainder being side walling on the banks. The height of the crest of the dam above the river bed is 26 metres, and the foundations go down some 10 to 12 metres. There are 80 sluices in the main structure, each 8·4 metres by 2 metres; and 14 sluices (each 5 metres by 3 metres) for the regulation of the irrigation canal. The quantity of masonry in the dam is 423,000 cu. metres. The reservoir has a capacity of 636 million cu. metres, or about one-quarter the capacity of the enlarged Aswan reservoir.

The Netherlands expedition to the Karakoram Range under the leadership of Mr. P. C. Visser made several important discoveries during the past year. From a preliminary account in the *Times* of January 18, it appears that from Hunza the expedition ascended the Hunza valley and then branched off into the Bara-Khun valley, which was found to drain a vast region of glaciers and peaks of more than 22,000 feet. Then the Khunjerab valley was ascended and a high but comparatively easy pass was discovered leading to the Ghujerab valley. From this valley, which proves to be occupied by the longest of the head streams of the Hunza, by a lofty pass the Shimshal valley was reached. At the head of this valley two great glaciers were discovered, the Khordopin, 32 miles long, and the Verijerab, almost as long. A third glacier, the Yazghil, which flows in from the south, was explored. Mr. Visser believes this heavily glaciated region to include the largest expanses of ice in the world outside polar regions. Other explorations included an ascent of the Batura glacier, which was found to be 37 miles long, and a northern branch of the Hispar glacier flowing from the southern side of the high peak of Malunguti. The expedition, in addition to mapping more than 2000 square miles, has made large scientific collections. A full account of the work is to be given shortly to the Royal Geographical Society.

An exhibit of models illustrative of flint flaking made by Mr. S. Hazzledine Warren will be held in the lecture room of the Royal Anthropological Institute at 52 Upper Bedford Place throughout the month of February, during the hours at which the Institute is open. Fellows and others who may be interested in the subject are cordially invited to visit this exhibition and examine the models. They number more than sixty, and are planned on similar lines to the models used in the study of comparative anatomy and other subjects. That is to say, they are painted in conventional colours to indicate the comparisons of homologous parts as developed under various human, mechanical, and natural processes of flaking. It is intended to make a limited number of duplicate sets of these models, as a first attempt towards a standard set for comparison. So far as good natural flakings are concerned, so few have yet been collected that, for the time being, museums generally do not, and cannot, possess adequate specimens. Although plaster casts are inferior to originals, it is hoped that they may prove better than none.

SIR GILBERT WALKER, the new president of the Royal Meteorological Society, succeeded Sir John Eliot as Director-General of Observatories, India, in 1904, and retired from that position after twenty years' service under the age rule. During his tenure of office as Director-General he attacked the complex problem that had puzzled all his predecessors, that of forecasting the monsoon rainfall, by the statistical method of using coefficients of correlation. His most noteworthy official contribution to meteorology is a memoir on "A Preliminary Study of World-Weather," in which he has collected together all the correlation coefficients, large or small, and has discussed the physical interpretation of his results. Sir Gilbert Walker was a senior wrangler and a fellow of Trinity College, Cambridge. He is now professor of meteorology at the Imperial College of Science and Technology, South Kensington, and has the distinction of being the only professor of meteorology in the British Isles.

LIEUT.-COL. E. GOLD, who was presented with the Symons Gold Medal of the Royal Meteorological Society at its annual meeting on January 20, is assistant director of the Meteorological Office, member of the Aeronautical Research Committee, and president of the Weather Telegraphy Commission of the International Meteorological Committee, 1919. He has carried out studies on the dynamics of the upper atmosphere, the thermal conditions of the stratosphere, etc., his researches in these subjects gaining him his fellowship of the Royal Society, and the prize, offered for competition to the whole world by the German Meteorological Society, for a discussion of the dynamics and meteorological statistics of the upper atmosphere. During the War he acted as organiser and chief of the British Meteorological Section of the Army in France, and was well known through the British Army areas as Meteor G.H.Q. This section was of enormous importance to the success of the Air Force and, more especially, the artillery.

SIR ERNEST RUTHERFORD received his education at the Nelson Boys' College and the Canterbury College, Christchurch, New Zealand, and on the occasion of his recent visit to Christchurch, he was presented with an illuminated address. It shows Sir Ernest Rutherford's school and college as they were when he attended them, the chemical laboratory in which he worked, and the house in which he was born. The wording of the address evidences the weight attached in Christchurch to scientific distinction, and the esteem in which Sir Ernest Rutherford is held in his native land. The decorations on the address are highly creditable to the artistic taste of the designer.

RAINFALL statistics over the British Isles for 1925 are given by the Meteorological Office, Air Ministry, in the monthly numbers of the *Meteorological Magazine*. The normal rainfall for the British Isles as a whole for the 35 years 1881 to 1915 is 41·41 inches, and the rainfall in 1925 for the several divisions of the British Isles is given as percentages of the normal. For the British Isles as a whole and in the divisions England and Wales, Scotland, and Ireland the rainfall was less than in 1924 and 1923. The mean for Great Britain and Ireland was 104 per cent. of the normal, the heaviest fall being 108 per cent. in England and Wales February had the greatest excess of rain over the normal in England and Wales with 189 per cent. and June the lowest with 6 per cent. of the normal. In Scotland, May had the greatest excess with 191 per cent. of the normal and June the lowest with 39 per cent. of the normal; in Ireland, May had the greatest excess over the normal with 194 per cent. and June the least with 23 per cent.; for the British Isles as a whole, May had the greatest excess with 185 per cent. of the normal and June the least with 18 per cent. of the normal. At Camden Square, London, the principal station of the British Rainfall Organisation, the rainfall for the year was 24·91 in., which is 0·44 in. more than the normal. The wettest month was July with 3·58 in. of rain, which is 150 per cent. of the normal, but relatively February had more abnormal rain, the measurement being 2·86 in., which is 171 per cent. of the normal. The driest month was June with 0·11 in., which is only 5 per cent. of the normal.

A NOTE on "Drought, its Prevention and Cure" is given in the *Meteorological Magazine* for December from an article on the Kalahari project by Prof. E. H. L. Schwarz. The author is well known for his proposals to increase the rainfall of South Africa by reconstituting the ancient lakes of the Kalahari region. Instances are cited of the extensive desiccation of large areas originally extensive lakes, and this is especially treated with reference to Africa. The author mentions that in Central Africa the great lakes still function as sources of rain for the interior, but he refers to imminent danger that Lake Victoria will be drained into Tanganyika, with disaster to the whole Nile Valley. Attention is directed to the water supply to the Kalahari lakes being intercepted through the Victoria Falls probably about 500 years ago. River piracy and geographical changes are possible and even probable; the part which concerns meteorology is the effect of such changes on rainfall. Reasoning on certain internal changes in South Africa, the author points to an average decrease of about one inch per annum in the rainfall between the periods 1881 to 1900 and 1901 to 1920. The author of the note refers to Bathurst having a decrease of nine inches per annum during the same period, and at Sierra Leone a decrease of 25 inches per annum. Even in the Cape Verde islands in the open ocean, the rainfall has suffered a marked decrease. These facts are taken to suggest that the disappearance of the Kalahari lakes is part of some more general change which human endeavour cannot hope to cope with. The article was the subject recently of an interesting discussion in the Meteorological Office.

THE recently published list of sectional presidents at the British Association meeting in Oxford next August has been completed by the appointment of Sir John Snell, chairman of the Electricity Commission, as president of Section G (Engineering).

AT a meeting of the Zoological Society of London held on January 20, it was stated that the total number of visitors to the Society's Gardens for last year was 1,823,618, a decrease of 233,528 as compared with the previous year. The number of visitors to the Society's aquarium during the period was 423,657.

HIS Majesty the King has consented to become patron of the annual general meeting of the Society of Chemical Industry to be held in London during the week commencing on July 19. The third Messel Memorial Lecture will be delivered by Lord Balfour at the Mansion House on the afternoon of the first day of the meeting.

A LIMITED number of bacteriological microscopes by Koristka are being offered for sale at a reduced price by Messrs. The City Sale and Exchange, Ltd., 81 Aldersgate Street, London, E.C.1. The microscope stand has a wide body tube fitted with draw tube, and is provided with a double rack-and-pinion coarse adjustment, a graduated fine adjustment, rotating stage, and a sub-stage with focussing adjustment. We have examined one of these instruments and consider it well made and capable of giving useful service in serious bacteriological or general microscope work. It is equipped with three objectives, $\frac{2}{3}$ in., $\frac{1}{6}$ in., and $\frac{1}{12}$ in. oil immersion, in triple revolving nose-piece, three eye-pieces, and an Abbe condenser with iris diaphragm. The price for the complete equipment in carrying case is 19 guineas, and the firm is prepared to supply the instrument on seven days' approval and also, if desired, to accept payment by instalments.

WITH reference to the note in NATURE of January 23 (p. 136), on the discovery of the capelin in glacial nodules in S.E. Bosnia, Mr. Errol I. White, of the Department of Geology, British Museum (Natural History), informs us that one of the specimens has been presented to the national collection by Dr. St. John Bolkey and is on exhibition at the Museum.

DR. R. B. MOORE, formerly chief chemist of the U.S. Bureau of Mines, who was largely responsible for the development of helium production during the War, has been awarded the Perkin Medal for 1925 by the American section of the Society for Chemical Industry. The presentation was made on January 15.

THE Rivers Memorial Medal for anthropological work in the field for 1925 has been awarded by the Council of the Royal Anthropological Institute to Prof. C. G. Seligman for work in New Guinea, Ceylon, and the Sudan. The Medal was presented to Prof. Seligman by Dr. A. C. Haddon at the anniversary meeting of the Institute on January 26.

IT is stated in the *Times* that in celebration of the centenary of the death of Stanislas Staszic, scientific worker, business man, and statesman, the Polish Government has restored to the Warsaw Scientific Society the palace presented to that body by Staszic, but afterwards confiscated by the Russians.

THE treatment of tuberculosis with sanocrysin, a thiosulphate of sodium and gold, introduced by Prof. Mollgaard of Copenhagen, has attracted attention, and Prof. T. R. Elliott details the results he has obtained with it in eleven cases (*Lancet*, January 16, p. 126). He thinks that, used with care, the drug does no harm, and his impression is that it produces more rapid improvement in pulmonary tuberculosis than could be obtained by any other method of treatment.

THE Council of the Geological Society has this year made the following awards:—Wollaston Medal to Dr. Henry Fairfield Osborn of the American Museum of Natural History; Murchison Medal to Dr. William S. Boulton, professor of geology in the University of Birmingham; Lyell Medal to Dr. O. T. Jones, professor of geology in the University of Manchester; Wollaston Fund to Mr. A. L. Leach; Murchison Fund to Mr. W. S. Bisat; Lyell Fund to Mr. F. Raw and Mr. A. F. Hallimond.

AN International Photographic Exhibition in Esthonia is being organised by the Esthonian Photographic Club in Tallinn (Reval) on May 2-16. Exhibits will be arranged in five sections: (1) Artistic photography, (2) photography in natural colours, (3) applications to science and industry, (4) photomechanical processes, (5) literature. Applications to exhibit must reach the Club by March 15 and exhibits by April 15. An illustrated handbook of the Exhibition containing also articles of professional interest is to be issued.

AT the annual general meeting of the Royal Meteorological Society, held on January 20, the following officers and new members of council were elected: *President*, Sir Gilbert Walker; *Vice-Presidents*, Capt. C. J. P. Cave, Col. H. G. Lyons, Dr. G. C. Simpson, Mr. G. Thomson; *Treasurer*, Mr. Francis Druce; *Secretaries*, Mr. R. Corless, Commdr. L. G. Garbett, Major A. J. H. Maclean; *Foreign Secretary*, Mr. R. G. K. Lempfert; *New Councillors*, Mr. R. Arnison, Miss E. Elaine Austin, Dr. H. Jeffreys, Mr. I. D. Margary, Lt.-Commdr. E. C. Shankland.

A meeting of the Society, which will take the form of a conversazione, will be held in the new galleries of the Science Museum, Exhibition Road, South Kensington, by invitation of Colonel H. G. Lyons, Director of the Museum, on Wednesday, February 3, at 5 P.M., to see the meteorological and physical collection. A gallery which has just been opened contains a large and effective display of meteorological instruments and weather charts, both modern and historical.

A CONVERSAZIONE will be held by the British Science Guild in the Carpenters' Hall, Throgmorton Avenue, E.C., by kind permission of the Master and Court of the Carpenters' Company, on Thursday, February 11, 4.30–6.30 P.M. Brief addresses will be given on the scientific approach in administrative problems, on the use and abuse of the "conference" instrument, on losses from avoidable fires, and on losses from timber disease. Admission will be by card of invitation only, to be obtained on application to the Secretary, British Science Guild, 6 John Street, Adelphi, W.C. 2.

AT the annual meeting of the Royal Microscopical Society held on Wednesday, January 20, the following officers and new members of council were elected: *President*, Dr. James A. Murray; *Vice-Presidents*, Mr. A. Chaston Chapman, Mr. M. T. Denne, Dr. R. J. Ludford, Sir Charles Parsons; *Treasurer*, Mr. Cyril F. Hill; *Secretaries*, Mr. Joseph E. Barnard, Dr. Clarence Tierney; *New Members of Council*, Dr. R. S. Clay, Dr. A. S. Parkes, Dr. A. Piney, Mr. E. A. Robins; *Librarian*, Mr. Robert Paulson; *Editor*, Dr. J. W. H. Eyre; *Curator of Instruments*, Mr. W. E. Watson Baker; *Curator of Slides*, Mr. E. J. Sheppard.

THE Council of the Institution of Electrical Engineers has made the fifth award of the Faraday Medal to Colonel R. E. B. Crompton, honorary member of the Institution. Colonel Crompton, who has twice been president of the Institution, is one of the early pioneers of electrical engineering and has played an outstanding part in the development of electricity supply in Great Britain. The Faraday Medal is awarded not more frequently than once a year either for notable scientific or industrial achievement in electrical engineering or for conspicuous service rendered to the advancement of electrical science without restriction as regards nationality, country of residence, or membership of the Institution.

THE New York correspondent of the *Times* announces that the Universal Oil Products Company has given a sum of 50,000*l.* to the American Petroleum Institute. This is in addition to the gift of 50,000*l.* made last December by Mr. Rockefeller, jun., for the encouragement of scientific research in petroleum. The Institute also announces that Mr. Charles E. Hughes has been retained to represent it before the Federal Oil Conservation Board.

WE are informed that Messrs. R. and J. Beck, Ltd., are opening new premises situated at 69 Mortimer Street, London, W.1. More accommodation will thus be provided for demonstration purposes in conjunction with microscopes and optical instruments.

WE have received from Messrs. Everett, Edgcumbe and Co., Ltd., an account of their exhibits at the Physical and Optical Societies' recent exhibition of apparatus, amongst which may be mentioned an integrating photometer for measuring by a single observation the mean-spherical candle-power of a lamp. The lamp under test is placed at the centre of a 3-ft. cubical enclosure with white interior walls, and a sample of the general illumination inside the enclosure is compared, in a photometer shielded from direct illumination, with that of an external lamp the distance of which from the photometer has been previously adjusted by comparison with a standard lamp at the centre of the enclosure. Another interesting feature was a 1000-amp. transformer for use up to the higher wireless frequencies. In this apparatus the secondary circuit and the magnetic circuit are enclosed within the primary current sheet, the primary circuit consisting of an entire copper sheath, which also serves as an electric shield.

MESSRS. Dulau and Co., Ltd., 34 Margaret Street, W.1, have just circulated Catalogue No. 136 of nearly 1200 works dealing with zoology, geology, and palæontology. Copies of the catalogue can be obtained free upon application.

MESSRS. W. Heffer and Sons, Ltd., Cambridge, announce the early publication of a new edition, the seventh, of S. W. Cole's "Practical Physiological Chemistry," containing two additional chapters on, respectively, biological oxidations and reductions, and the analysis of blood.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A principal of the Chesterfield Technical School—The Director of Education, St. Mary's Gate, Derby (February 8). A lecturer in the department of Civil Engineering and Surveying at the Imperial College of Science and Technology, City and Guilds (Engineering) College—The Secretary to the Delegacy, City and Guilds (Engineering) College, Exhibition Road, S.W.7 (February 15). Sir Ernest Cassel readerships at the London School of Economics in economic geography and in foreign trade—The Academic Registrar, University of London, South Kensington, S.W.7 (February 18, *not* March 9 as previously announced). A scientific assistant at the Royal Aircraft Establishment, primarily for research in connexion with electrical ignition appliances—The Superintendent, R.A.E., South Farnborough, Hants (February 20) (quoting A.81). A curator of Museums under the Libraries, Museums and Arts Committee of the City of Liverpool—The Town Clerk, Dale Street, Liverpool (February 27) (endorsed "Curator of Museums"). A professor of metallurgy in the University of Birmingham—The Secretary, University, Birmingham (March 1). A professor of physics at University College of North Wales—The Registrar, University College of North Wales, Bangor (March 20).

Our Astronomical Column.

NEW COMET.—Another new comet, 1926*b*, was discovered at Braamfontein on January 16, by Mr. T. E. Blathwayt, who immediately communicated the news to the Union Observatory at Johannesburg, where an observation was secured a few hours later. The comet was then in Declination 30° South, but it was moving rapidly northward, and will be observable in England when the moon approaches new. Observations by Mr. Jeffers at the Lick Observatory, and M. Renaux at Algiers, have come to hand. From these Dr. A. C. D. Crommelin has computed the following orbit:

$$\begin{array}{l} T\ 1926\ \text{Jan.}\ 3{\cdot}3481\ \text{U.T.} \\ \left.\begin{array}{llll} \omega & 328^\circ & 41' & 57''{\cdot}6 \\ \Omega & 136 & 3 & 58{\cdot}2 \\ i & 128 & 22 & 2{\cdot}8 \end{array}\right\} 1926{\cdot}0 \\ \log q\ 0{\cdot}129327 \end{array}$$

EPHEMERIS FOR 0^h.

	R.A.	Decl.	log r.	log Δ.

The magnitude was 11 at discovery; the approach to the earth will probably cause a slight brightening.

PROF. W. H. PICKERING'S WORK ON MARS.—The Draper 11-inch refractor with which Prof. Pickering has observed six apparitions of Mars since 1912 at Mandeville, Jamaica, has now been recalled to Harvard. Though he hopes to observe the next apparition there with another telescope, he thinks it is a good occasion to summarise his results. A paper in *Popular Astronomy* for November 1925 contains his measures of the polar caps. As has previously been noted, the circumpolar regions are veiled with clouds when the cap is forming, which takes place fairly rapidly. Then the clouds disperse, leaving the dazzling snow surface visible.

Owing to the eccentricity of the orbit the southern cap is larger than the northern, but melts more quickly. A great fraction of the total moisture of the planet, which Prof. Pickering estimates as about equal to that in the great American lakes, is concluded to oscillate between the two polar regions, fertilising each hemisphere when it melts.

Prof. Pickering alludes to the results obtained by Drs. Adams and St. John with the Mt. Wilson 60-inch mirror (*Pub. Ast. Soc. Pac.*, 1925, 37, 158). They find that the water vapour in Mars' atmosphere is of the order of 5 per cent. of that in our own, and the free oxygen 15 per cent. of that in our own. These facts, combined with the thermopile results indicating a fairly high day temperature, suggest that the conditions for habitability are more favourable than were supposed some years ago.

RECENT SUNSPOTS.—The two large groups of sunspots which were seen during the latter half of December have returned as naked-eye objects. The preceding spot, south of the sun's equator, represented the following of the two spots originally composing the group. The great spot in the northern hemisphere has returned increased in extent, and on January 19 and 20, although much foreshortened near the sun's limb, it was easily seen with the naked eye. This single spot is one of the three largest which have appeared within the last fifty years. Its area on these two days exceeded 3000 millionths of the sun's hemisphere; its length, 8½ degrees of solar longitude, is equivalent to about 60,000 miles.

There have been other spots of minor importance. The large stream of spots, seen on the central meridian on December 16, has returned though much diminished, and the leading spot of an earlier stream (central meridian passage, November 24) has been seen for the third time.

The following table continues the information of naked-eye spots:

No.	Date on Disc, 1926.	Central Meridian Passage.	Latitude.	Maximum Area.
1	Jan. 16–29	Jan. 22·3	21° S.	1/1000
2	Jan. 18–31	Jan. 24·6	22° N.	1/300

(Areas express the proportion covered of the sun's hemisphere.)

AUTOMATIC REGISTRATION OF STAR-TRANSITS.—The problem of making the stars automatically record the time of their transit over the wires of a transit circle is an attractive one, to which many astronomers have devoted some thought since the introduction of photography as an aid to stellar observation. Mr. Bengt Strömgren, son of Prof. E. Strömgren, director of the Copenhagen Observatory, describes in *Astr. Nach.*, No. 5406, some experiments that he has made in this direction, using the very sensitive photoelectric cell which is now widely employed for stellar photometry. The current through the cell is so weak that amplification of the order of 10^8 is necessary to operate a chronograph. The widespread use of wireless telephony has gradually brought about improved methods of amplification. Broad occulting bars in the focal plane of the telescope take the place of spider lines; the disappearance and reappearance of a star is automatically recorded.

Successful experiments have already been made on α Arietis (mag. 2·2) and the theoretical feasibility of the method is thus demonstrated; but it is doubtful whether it could be carried below magnitude 5. Moreover, there would seem to be a danger of re-introducing magnitude equation, which has been practically eliminated by the use of the travelling-wire micrometer.

MEASUREMENTS OF RADIATION IN THE SOLAR CORONA.—An important series of measurements of solar corona radiation were taken during the total eclipse of January 24, 1925, by E. Pettit and S. B. Nicholson, who describe their work in the *Astrophysical Journal*, vol. 62, p. 202. The instrument used was a thermocouple placed at the focus of a reflector 50·5 cm. in diameter. A rock-salt window was used for the thermocouple, but observations point conclusively to the fact that there is no appreciable radiation of longer wave-length than 5·5 μ from the corona, so that, in the future, quartz or glass windows may be used without loss. Photometric measurements of direct photographs of the corona were also made, with the object of investigating the distribution and total amount of the radiation. These results were calibrated and expressed in absolute units by comparison with the radiometer measures at selected points. The total light from the corona as measured in this manner was found to be $11{\cdot}2 \times 10^{-7}$ that from the whole sun, or 0·52 of the light received from the full moon at mean distance; one-half of this light coming from a zone extending only 3′ from the limb of the sun. There seems to be very little hope of detecting the corona by radiometer measures without an eclipse, unless the amount of scattered sky-radiation can be reduced to at least 1 per cent. of its value, as observed on Mount Wilson.

Research Items.

The Origin of the American Indian.—In the Smithsonian Report for 1923 (dated 1925), Dr. Aleš Hrdlička, after setting forth the grounds for his view that the American Indian is a race, homogeneous on the whole, which penetrated the continent from Asia through the north-west in relatively modern times, goes on to discuss the chronology of this intrusion and the relative priority of the various types of the Indian race. He points out that the remains, archæological and skeletal, of north-eastern Asia are of no great antiquity, but correspond generally to those of the Old World Neolithic age. The palæolithic remains of the Yenisei and north-western China are thousands of miles away from the point where man crossed to America. This leads to the presumption that man did not cross over before late Palæolithic or early Neolithic times This would give a date of about ten or at most fifteen thousand years ago. Even if the unlikely hypothesis were accepted that man of north-eastern Asia had an independent development from European late Palæolithic or Neolithic man, his advent from southern Asia could not have been earlier than if he had come from the west. Mass migration being impossible owing to the difficulties of climate and food supply, the people must have passed over in small groups. Of these, the first would be the dolichocephalic Indian represented by the Algonquian, Iroquois, Sioux, and Shoshonean stocks which spread to Tierra del Fuego, including the Lagoa Santa race. Next came the "Toltec" type marked by brachycephaly, settling along the north-west coast and reaching as far as Peru. Later came the Eskimo and Athapascan, the former spreading over the far north and becoming the most highly specialised of American types, while the Athapascan, a virile brachycephalic type which may have preceded the Eskimo, is the most closely allied of all to the prevailing Mongolian type of north-eastern Asia. The path of the Athapascan was blocked and they remained in Alaska, except for a few who passed along the west coast to Mexico, where they left the Hupa, and to New Mexico, Arizona, Texas, and tracts of northern Mexico, where they are known as the Apache.

Prehistoric Amber Routes in Europe.—The relative rarity of amber, and the peculiarity of Baltic or northern amber generally owing to its high content of succinic acid, has opened an important line of archæological research in tracing ancient trade routes, based on discoveries of amber, between northern and southern Europe. In the *Geographical Journal* for December, Mr. J. M. de Navarro gives some of his conclusions. Evidence is not sufficient to warrant the assumption that there was a transcontinental trade in amber prior to the Bronze Age. Before that time the appearance of amber in the south was sporadic, and it probably came by sea. In fact, it was not unlikely the opening of the amber trade that led to the introduction of bronze to the north. During the middle Bronze Age, southern and western Germany seem to have played a larger part in the trade than Italy, yet it was probably through Italy that Baltic amber reached the Ægean world. There is not sufficient evidence to say that it came by way of Russia. During the early Iron Ages, the commerce with Italy grew, and consequently Italian influence in northern Europe was more direct. Italian amber was exploited at that period, but analysis of specimens warrants the belief that more of the amber in Italy came from the north, while a certain amount of inferior Italian amber was traded in Switzerland. Mr. Navarro believes that the amber trade culminated about the middle of the seventh century B.C. After that the eastern superseded the western routes and the trade lost importance.

Climatic Changes and the Wegener Theory.—The Wegener theory receives warm commendation in an interesting article by Dr. G. C. Simpson on "Climatic Changes" in the January issue of the *Nineteenth Century*, on the ground that it "solves so many meteorological problems that it is difficult for meteorologists not to accept it." The most serious of these problems is the uniform world-wide climate during the Jurassic claimed by Prof. A. C. Seward from the plant evidence. This view Dr. Simpson describes as "entirely inexplicable" to the meteorologist. It is also inexplicable to the geologist in face of the evidence by the Jurassic faunas of well-marked climatic zones parallel to those of the present day, and of the refrigeration of the Jurassic climate toward the polar regions. The reef-building corals, for example, were then prolific in tropical and subtropical seas, but gradually disappeared toward the north. Dr. Simpson discusses the evidence for recent changes of climate, and agrees with Prof. J. W. Gregory's conclusions that there has been no progressive desiccation or permanent change of climate of the earth during the past 3000 years, though there have been local variations greater than those of the Brückner cycle. Dr. Simpson states that all subsequent work has confirmed Brückner's 35-year climatic oscillation; but as the irregular local changes exceed the Bruckner variation, it is only apparent in records over an extensive area. Dr. Simpson suggests that the oscillation should be called the Brückner groups of cold and warm years rather than a cycle.

Functional Diseases of Apples in Cold Storage.—The Food Investigation Board publishes as Special Report No. 23 ("Functional Diseases of Apples in Cold Storage." By Franklin Kidd and Cyril West. Pp. vi + 15 + 13 plates. London: H.M. Stationery Office, 1925. 1s. net), a very useful summary of the various diseases known to occur to apples in cold storage. This report is based upon a paper by Drs. Franklin Kidd and Cyril West which was published in the *International Review of the Science and Practice of Agriculture*, which is now brought up-to-date and reprinted as a special report accompanied by an extensive series of photographs greatly facilitating recognition of the various diseases. Basing their views in part upon causal conditions involved in orchard conditions or cold storage practice, and in part upon methods of control, the authors recognise the following main types of disease: (1) Apple scald, a browning of the skin of the apple, a disease of the green skin, to which red and yellow skins are very resistant, which can be controlled by very efficient aeration or, still better, by wrapping the apple in a tissue paper that has been soaked in mineral oil. American investigators suggest that this disease is due to the accumulation of esters at the apple surface which are volatilised with efficient aeration or absorbed by the mineral oil. (2) Internal breakdown, a browning of the flesh of the apple which can be controlled by storing at somewhat higher temperatures than 32° to 34° F. (3) Brown heart, caused by excessive accumulation of carbon dioxide during storage (see Nature, April 18, 1925, p. 584), which is avoided by preventing accumulation of carbon dioxide so high as 8 per cent in the storage atmosphere. (4) Frost injury, usually local unless freezing has been severe. An interesting point recorded here is the relatively severe damage that is caused by bruising when the apples are in the frozen condition. The freezing point of the majority of apples appears to be between 28° F. and 30° F.

THE BRITISH FRESHWATER PEARL MUSSEL.—A short while ago (NATURE, July 25, 1925, p. 148) we directed attention to Part I of Mr. J. Wilfrid Jackson's excellent address to the Conchological Society on "The Distribution of *Margaritana margaritifera* in the British Isles." Part II., now before us, which was announced to deal with the past history of the mollusc, does not, however, attain the same standard of excellence or add much to what little was known on the subject. The author points out that there is no definite proof of the occurrence of Margaritifera in pre-glacial times, and concludes that the species owes its presence to dispersal since glacial times, spreading gradually as the glacial conditions were passing away from areas untouched by the ice-sheets and gradually attaining its present distribution. Mr. Jackson summarises and discusses at some length the opinions of a limited number of writers on the glacial period and seems to conclude in favour of the post-glacial age of the greater part of the British fauna and flora. This to one with some fifty years' acquaintanceship with the subject has a distinct flavour of antiquity about it.

COLOUR VARIATIONS IN PARTRIDGES.—An exceedingly instructive series of colour variations in the red-legged partridges, *Alectoris rufa* and *A. saxatilis*, are described by Messrs. W. and G. Bateson (*Journ. Genetics*, vol. 16, No. 1). The "bright" variety of *A. rufa*, known as *melanocephala*, is represented by four specimens in the British Museum, all from the west of England, where four others have been seen. This form is also known from two records in different localities in Spain; and three specimens of the same variation in *A. saxatilis* were examined in Swiss museums, having all been taken within a radius of thirty miles. A "dull" variety of *A. rufa* is described under the name *obliterata*. It has a more nearly uniform coloration and is represented by three male specimens, all from the east of England. A black-headed species exists in Arabia under the name *A. melanocephala*, and this may be factorially significant. The dull, normal and bright forms are regarded as forming a series showing the progressive spread of barring. They are compared with the varieties of North American flickers, Colaptes, and with the barred patterns of the quagga and its relatives. As with Colaptes, a consistent factorial analysis of the differences is impossible without breeding experiments, because the colour-changes in different pterylæ appear to be, at least in part, independent of each other. The same problem is involved here as in the origin of many species which differ in several features of their colour patterns. Many South American parrots and parrokeets show similar differences, and it is to be hoped that some one will undertake breeding experiments with them, which might throw much light on the nature of all such variations.

THE ANATOMY OF PILA.—Vol. 8, No. 3 (1925), of the *Memoirs of the Indian Museum* is devoted to a description, by Dr. B. Prashad, of the anatomy of the common Indian apple-snail, *Pila globosa*, one of the Ampullariidæ which inhabits tanks, ponds, lakes, streams, and ricefields in the Gangetic plain, being particularly abundant where there is a large quantity of succulent aquatic vegetation. The various systems of organs are carefully described and references made to the histology. The functions of most of the organs are briefly noticed, *e.g.* the methods of respiration, aquatic and aerial, and short biological notes are added. The memoir will be found useful for comparative purposes.

CARBOHYDRATE/NITROGEN RELATION IN HORTICULTURE.—The *Journal of Pomology and Horticultural Science* for December contains an interesting review of recent American investigations on the importance of the carbohydrate/nitrogen balance in the plant, upon processes of growth and reproduction, which is written by Henry W. Hooker of the University of Missouri, who is himself an active worker in this field. This ratio is somewhat vague in connotation; carbohydrate is commonly used to include both insoluble polysaccharides such as starch, and reducing sugars, but not substances entering into the skeleton of the plant; there is some discussion as to whether soluble, insoluble or total nitrogen figures are more relevant. By various practical methods, as manuring, girdling, pruning, root pruning, and so on, this ratio can be definitely disturbed and in terms of the disturbance the effects upon growth and reproduction interpreted, though it is evident that the metabolic changes may be associated with, and yet not causal in relation to, growth and developmental changes. In fruit trees it has now been clearly demonstrated that in different parts of the tree this ratio may have a very different value and that the initiation of flower buds is associated with relatively high carbohydrate, whilst, on the other hand, fruit development seems associated with a rise in nitrogen in the fruit-bearing spurs.

THE ORIGIN OF THE ALPS.—In a paper recently read before the Royal Geographical Society, Prof. L. W. Collet gave a summary of recent ideas with regard to the evolution of the Alps. In a series of diagrams, to be published later in the *Geographical Journal*, he showed that in the embryonic Alps the foreland and hinterland of the chain constitute the boundaries of the great Alpine geosyncline diversified by included geanticlines. Through Carboniferous and Jurassic times these boundaries closed on and compressed the geosyncline like the jaws of a vice. The two geanticlines have developed into the two dominant nappes of the Alps, Great St. Bernard and Dent Blanche. Prof. Collet accepts as proved the forward drive of the hinterland towards the foreland. These conclusions, he points out, are in support of the Wegener hypothesis and indicate a northward drive of Europe, producing a distension to which the Mediterranean basin is due.

THE SPECIFIC HEAT OF ROCKS.—The effects of heat upon rocks are important not only geologically but also from the point of view of their fire-resisting properties. A valuable investigation which should not be overlooked has been carried out by T. Okaya, and the results are published in the *Japanese Journal of Astronomy and Geophysics*, vol. 3, No. 1, 1925. The specific heats of seventy-one different rocks are given, with a careful petrological description of each of the specimens tested. It is shown that the specific heat depends mainly on the chemical composition, but also in part on the structure. For practically all rocks the value lies between limits of 0·1 and 0·3. Among igneous rocks those rich in soda have higher values than those rich in potash. Sodic andesites, for example, range from 0·24 to 0·28, whereas potassic andesites range from 0·14 to 0·20. Crystalline limestones vary widely: from 0·19 for those poor in calcite to 0·26 and higher in the case of saccharoidal calcite marbles. Results are also recorded for tuffs and granites, and the paper is illustrated by eighteen excellent photo-micrographs.

AN AIR-PRESSURE SOUNDING MACHINE.—In the November number of the *Hydrographic Review*, there is a description of a self-recording sounding machine which depends on balancing the pressure of water on the sea-bottom by an equal pressure of air. The portion on the sea-bottom is an armoured sounding cable containing a flexible rubber tube. The lower end of the cable is provided with a jointed armoured covering which permits ready bending and promotes durability. The inboard end is secured by an air-tight joint to the hollow axle of the winding drum. An air-pressure-pipe connects the axle, and therefore the tube of the sounding cable, with a pressure gauge on the bridge and with the compressed air reservoir. The recording devices consist of three dials and a bathygraph. The depth, at any moment, can be read on one of the dials. The other dials show the amount of cable out and the pressure in the air reservoir, while the time is recorded on a bathygraph. In practice the pressure in the reservoir is kept slightly higher than any water pressure expected, and the excess pressure is reduced by the escape of air from the bottom end of the sounding cable until the water pressure is balanced.

Stokes's Theory of the Aberration of Light.—The issue containing parts 11-14 of Vol. 58 (1925) of the *Rendiconti of the Royal Lombardy Institute of Science and Letters* includes a paper by Prof. G. A. Maggi replying to the objections raised to Stokes's theory of the aberration of light by Prof. Eddington in his communication on "Ether Drift and the Relativity Theory" published in Nature of June 6 last. As regards the first objection—that the ether, with a velocity which is zero at sea-level and 10 kilometres per second at the height of Mount Wilson, would possess a rapid rotational motion, whereas Stokes showed that the movement of the ether should be irrotational—Prof. Maggi points out that actually Stokes postulated the irrotational movement to deduce his formula and that hence arose a difficulty indicated at the time by Lorentz in his paper on "Stokes's Theory of the Aberration in the Supposition of a Variable Density of the Ether" (*Proceedings of the Royal Academy of Sciences*, Amsterdam, 1898–1899, p. 443). The second and more serious objection advanced by Eddington is to the effect that, in contradiction to the more elementary notions of astronomy, the formula of Stokes indicates a variation of the aberration with the altitude. In this connexion Prof. Maggi observes that Stokes's formula furnishes the effective deviation, with respect to the terrestrial globe, of the light emitted from a star, from which, allowing for the degree of drag of the ether at any altitude, the aberration at that altitude is deduced.

Release of Pressure in Coal-dust Explosions.—"The Effect of Release of Pressure on the Development of Coal-dust Explosions" is the subject of the second joint publication by the Safety in Mines Research Board and the United States Bureau of Mines (London, H.M.S.O., 3*d*. net). It describes a series of trials carried out at Eskmeals under Dr. R. V. Wheeler, the Director of the Station, and Mr. H. P. Greenwald of the Bureau of Mines staff. The experiments were made in the large steel gallery 750 feet long, open at one end and (normally) closed at the other. A cannon fixed 200 feet from the closed end was fired into a pile of fine coal-dust placed in front of it. Between the cannon and the open end, 550 feet away, fine dust was strewn partly on side-shelves and partly on the floor; no dust was laid behind the cannon. Along the gallery timing-screens and pressure gauges were fixed. The release of pressure was effected by substituting plates with circular holes cut in them for the solid plates which normally closed the gallery at three different places. (1) In the first place the release was made in the end plate 200 feet behind the cannon. When this was closed the maximum velocity of flame recorded near the mouth of the gallery was 2660 feet per sec. with a maximum pressure of 73 lb. per sq. inch. When this plate was a quarter open, little difference was observed; but with the end half open the pressure recorded was much less, although the flame came out at both ends of the gallery. With the rear end quite open the flame travelled slowly and only 2 lb. pressure was recorded. (2) When the openings for release were made just in front of the cannon, two small openings of one-sixteenth the area of the gallery had little effect on the velocity and pressure; but two one-eighth openings reduced the velocity to nearly one-quarter and the pressure to 3 lb. On moving the cannon just in front of the two one-eighth openings the velocity was high and the pressure rose to 23 lb. (3) When the openings were 200 feet in front of the cannon, the effect was to accelerate the initial flame, though the pressure recorded near the open end was not so high as when there was no release—and appeared to diminish as the flame proceeded. The nearer to the firing-point the release of pressure can be made, the greater is its effect in preventing a serious dust explosion.

Alchemical Secret Names.—E. Wiedemann and J. Ruska have accomplished a very useful piece of work in giving a list of some Arabic alchemical "Decknamen" in a recent number of the *Beiträge zur Geschichte der Naturwissenschaften* (Sitzungsber. d. Physikalisch-Med. Sozietät in Erlangen, Band 56, 1924) It is well known that the Greeks, Syrians, Persians, Arabs, and others who, during 2000 years, busied themselves with alchemy, used "technical" or secret names for the substances they used in their operations These names sometimes refer to noticeable properties of the bodies concerned (*e.g.* mercury, "the volatile slave"; copper, "the green one"; and so on), and sometimes are derived from mystical or religious associations, as when the metals are called by the names of the planets. Very often, however, they are purely arbitrary, so far as can be judged at the present day. The existence of this peculiar and variable system of nomenclature renders the translation of early chemical texts a matter of great difficulty, and the appearance of any list of synonyms—especially from the pen of Wiedemann and Ruska—is a matter for congratulation. The present paper is based mainly upon a manuscript work (Berlin, Ahlwardt's catalogue, No. 10361) of the celebrated poet, statesman, and alchemist Al-Tughrā'ī, entitled "The Book of the Precious Stone, upon the Art of the Elixir," but other sources have been drawn upon as well. First of all, the various names of the seven metals are given—no less than 23 for gold and about 60 for mercury!—then come the names of the seven "spirits" (mercury—also classed with the metals,—sal-ammoniac, realgar, orpiment, "yellow sulphur," "red sulphur," and "white sulphur"). Among the most interesting are the following: *Al-Kātib* (the scribe) and *Ḥayatu'l-Ajsād* (life of the metals), for mercury; *Al-Milḥ al-Ṭayyār* (the flying salt) and *Al-Filfil al-Armanī* (Armenian pepper) for sal-ammoniac; and *Ṭair Suqrāṭ* (the Bird of Socrates) for sulphur. A similar vocabulary, but with a larger proportion of Greek names, is given by the thirteenth-century author Abu'l-Qāsim al-'Irāqī in his book "Al-Kanz al-Afkhar," a MS. of which is preserved in the Royal Library at Cairo. Such lists are not only interesting in themselves; they also afford useful evidence concerning the transmission of chemical knowledge from one nation to another. Very noteworthy is the large number of Persian words used by Muslim chemists.

The Mathematical Association in Conference.

THE annual meeting of the Mathematical Association was held at the London Day Training College on January 4 and 5, with Prof. G. H. Hardy presiding. The report of the Council records continued growth in membership, and continued activity on the part of committees. The programme of the meeting consisted of three lectures and two discussions, in addition to the president's address.

Prof. E. N. da C. Andrade, whose subject was atomic structure, described the decomposition of a line spectrum into series, and Bohr's theory of the relation of these series to the constitution of the atom.

A lecture on modern theories of integration was in the nature of an experiment, and was brilliantly successful. After recalling the dual rôle of the integral in elementary work, Mr. Carey Francis showed the limitations imposed by any definition of the definite integral in which the only division of the range which is contemplated is a division into subintervals He explained how the measure of a set of points extends the conception of the length of an interval, and introduced the Lebesgue integral and the Stieltjes integral as natural results of subdividing the range of integration into sets of points of any kind instead of into intervals only. Mr. Francis' achievement in making clear the nature and purpose of a mathematical method that was outside the curriculum in the student days of the majority of his audience seems to indicate a new and valuable function of the Association.

A forcible speech by Mr. E. R. Brown opened a discussion on the *Mathematical Gazette*, the organ of the Association; the remarks of different speakers emphasised the variety of tastes for which an editor may be asked to cater, without showing very clearly the sources from which he can draw.

Dealing with the measurement of intelligence, Prof. C. Spearman first illustrated the difficulty of reaching agreement either on a simple definition of intelligence or on the group of elementary qualities to be included in a composite definition. He afterwards explained the discovery that over a very wide range the observations can be systematised by the recognition of two factors, one which can be regarded as a measure of general intelligence and another which depends on the subject in which the individual is being tested.

The president's address was entitled "The Case against the Mathematical Tripos." Examinations have their place in education up to a certain point as natural and effective tests of industry and of the ability to learn and to reproduce, but the claim made for the Tripos has been that it assesses qualities of a higher order. Because of this claim and of the prestige of the Tripos, training for the examination has been substituted for genuine mathematical education, with the mischievous result to the individual that at any time it has been possible to obtain the highest honours while completely ignorant of all the broad developments of the previous thirty years, and to the nation that in no subject except music has the international position of England been so deplorable throughout two hundred years as in mathematics. Not only is it difficult to present in theory a plausible defence of the claim made for the Tripos, but in practice, position in the Tripos is ignored in all but an insignificant fraction of appointments, and if the Tripos is less harmful to English mathematicians now than fifteen years ago, that is because there is no distinction now which a good student does not obtain as a matter of course. Convinced that the best that can be said for the Tripos is, that so long as no attention whatever is paid to it either inside the University or outside, its ill effects are negligible, Prof. Hardy advised mathematicians at Cambridge deliberately to lower the standard at every opportunity, and so to reduce the examination to an absurdity the abolition of which must be only a matter of time.

Time was allotted for discussion of a "Report on the Teaching of Mathematics to Evening Technical Students," which has just been prepared for the Association; unfortunately, the report was not in the hands of members, and speakers could refer only to a synopsis distributed at the meeting, but interesting views were expressed on such matters as the value of deductive geometry for these students, and appropriate methods of introducing logarithms and the exponential function.

Agricultural Education in the United States.[1]

DURING the last half-century the importance of agricultural education has been increasingly recognised in America, until now every State has one or more agricultural colleges, forming a group of institutions occupying a prominent position in the field of education. During the decade 1910–1920 development was extraordinarily rapid, and very large sums of money were appropriated in many States for the provision of new agricultural buildings, the purchase of land, and the endowment of educational programmes. The colleges have had a long struggle for recognition, but have demonstrated their value and are now in such a position, financial and otherwise, that their future usefulness is assured. The immediate need is for trained teachers, investigators, and administrators, and in response to this, graduate work in agriculture has developed with amazing rapidity during recent years, though in certain colleges it is still seriously handicapped by lack of funds and accommodation. At present the full agricultural course extends over four years, but there is a suggestion to extend this to five in some cases for the purpose of specialised training. In many colleges the curricula have been steadily changed in order to keep abreast of the modern requirements of agricultural education, though there are still some in which the work is too largely restricted to methods of production, resulting in a narrowed outlook.

The field of work covered is very wide, ranging over at least a dozen branches, which, however, are not rigidly separated but dovetail into one another to some extent. All branches have developed from small beginnings, shaping themselves according to the needs of the time, with the result that some subjects which were originally an integral part of one branch are now dealt with more fully and adequately by others. Agronomy was initially defined as covering that part of the general field of agriculture devoted to climate, soils, fertilisers, and farm crops, but it now tends to deal with the more fundamental and far-reaching problems of soil physics and chemistry, plant physiology, and plant genetics. It is claimed that the instruction in agronomy has had much to do with securing the improved crop production of the United States in recent years. Horticulture has almost always had a separate existence in the colleges, but with the growth of various interests, certain branches have developed until now they are treated independently, pomology and vegetable gardening being notable examples. With the better recognition of the importance of the forests to the nation, the instruction of forestry has advanced from exclusive concern with questions of afforestation to consideration of the vital problems of the proper protection, management, and perpetuation of existing stands of timber. The land grant colleges recognise their opportunity and responsibility to train the leaders with the necessary technique and with the broad outlook which will enable them to develop sound public policies of dealing with the forests and to establish right standards of practice. The general scheme of education keeps in view both the scientific and practical aspects of agriculture, and endeavours to emphasise the entire interdependence of the two. In addition to the branches already mentioned, special sections are devoted to soils and fertilisers, plant pathology, entomology, animal, dairy, and poultry husbandry, veterinary education, and agricultural engineering.

---

[1] Land Grant College Education, 1910–1920 Part III.: Agriculture. Edited by W. C. John. U.S. Bureau of Education Bulletin, 1925 No. 4. Pp. 105.

It is recognised that the four-year college course is not sufficient to supply the demand for trained workers on the land, partly because so large a percentage of graduates draft off into other occupations, as teachers, county agents, scientific workers, etc., and partly because a large proportion of those intending to farm cannot afford the time or money for a full college training. To meet the needs of the latter class, various types of short courses have been developed covering the various sections of the community concerned. The older boys and girls are catered for by special agricultural schools, farmers are provided with short courses extending over a few weeks only, at the slackest times of the year, and short schools are held for training specialists in such subjects as dairying, cotton culture, and ice-cream manufacture. In addition, courses in agriculture and horticulture are run for one, two, or three years, primarily for young men and women who intend to make farming their life work. Many problems have arisen in the development of these short courses, and special endeavours are made to solve them in such a way as to render the courses an integral and valuable part of the whole educational scheme.

During recent years a very marked development has taken place with regard to the professional training of teachers in agriculture. Special legislation has provided grants from Federal funds for the purpose, on the condition that equal sums are found by the States participating. The expenditure in this respect increased from 121,244 dollars in 1918 to 651,792 dollars in 1921, the growth of the work being so rapid that it was difficult for the land grant colleges to secure adequately prepared instructors for the purpose. Still more recently a demand has developed for courses in education designed to meet the needs of college instructors, and there seems little doubt that this part of the work will increase in relative importance The same may be said of the agricultural extension work, which has steadily increased until in 1921 more than 18 million dollars were expended thereon, directly aiding the improvement of the farm and home practice of more than two million workers directly connected with the land, the whole of the extension work in 1920 costing 75 cents for each 1000 dollars of gross returns from agricultural production in the United States.

The Rainfall of Dry Periods in Relation to Water-power Schemes.

IN all questions relating to water-power schemes, some estimate of the water available is of first importance. Most schemes involve the storage of water in reservoirs, the size of which depends on the proposed draw-off compared with the run-off from the gathering ground in a dry period. Undoubtedly measurements of stream flow afford the best hydrological data upon which to base calculations. Such data are, however, often too short to give the average over a long period or the flow in the all-important dry period. Thus to a large extent calculations have to be based upon measurements of rainfall, compared where possible with gaugings of stream flow. It is, therefore, important to consider the relation of the average rainfall (1) to that of the period for which stream gaugings are available, and (2) to falls in dry periods in that area.

An investigation has been carried out on this subject by Capt. W. N. McClean,[1] who has analysed the monthly and annual rainfall figures for the fifty years 1871 to 1920 for thirty-five stations in Scotland. This mass of data is marshalled into a convenient graphical form, the unit of measurement of rainfall being expressed throughout in inches per annum, and the rainfall being plotted as the aggregate excess or deficiency from the average of the whole fifty years. The curves reproduced in the paper make it possible to read off.

(1) The actual rainfall of each calendar month and year;

(2) The lowest rainfall of each month and year; and

(3) The predicted lowest falls of periods of various lengths based on (2) above.

The fifty years, 1871 to 1920, were remarkable for the run of wet years in the 'seventies, the years 1872 and 1877 being the wettest in the series. The rainfall of the years 1886 to 1889, especially that of 1887, provided in many cases the lowest values in the period under discussion and would have severely taxed the storage capacity of the reservoirs. Outside the series, the year 1870 was as dry as 1887 over Scotland as a whole, while 1921 was noteworthy for the lowest annual totals on record in parts of the east of Scotland. Had these years, 1870 and 1921, been included in the analysis, lower values would certainly have been obtained in some instances and the smoothed enveloping curve of predicted values might have been modified.

One of the important facts brought out by the paper is that the rainfall at some stations is more variable year by year than at others, and this characteristic persists throughout the fifty years. The mean deviation of annual rainfall from the average is known to exceed 12 per cent. in central and south-eastern Scotland. This value diminishes towards the coast on all sides, but especially to the north-west, where, in islands to the west of Scotland, the value is only 8 per cent. This small variability factor in the rainfall of parts of Scotland is of considerable importance in connexion with the supply of storage reservoirs. In arriving at the predicted lowest values for each record, a factor is used based on the mean lowest value for the thirty-five gauges. Since there is this marked geographical variation, it would clearly be advantageous to use a factor varying with the geographical position of each individual station.

The curve of lowest predicted values is obtained from the one extreme value of the low rainfall for each of the periods of varying length. It is, however, essential to know the frequency of occurrence of low readings and whether any of them are fortuitous. Such information can be readily obtained from the mean deviation, which takes account of all the deficiencies in the series. This is another reason for including some such measure of the variability of the rainfall in the curve of the predicted lowest values.

---

[1] "An Analysis of Scottish Rainfall Records" By W. N. McClean. Pp. 19+16 plates. (The Institution of Water Engineers, December 1925.)

This exhaustive analysis of Scottish rainfall is of particular importance in that the Western Highlands of Scotland provide a promising field for the further development of water-power schemes, having a large area with an average annual fall of more than 80 inches (reaching locally 150 inches) and a smaller factor of variability than most other areas in Great Britain.

The Spider Crabs of America.[1]

MISS RATHBUN has completed a very beautiful systematic monograph on the American spider crabs. It is a work of enormous labour, for no less than seventy-nine genera and nearly three hundred species are described, with minute details of their distribution and lists of the specimens examined from all localities. The figures are good photographs or clear diagrams and occupy nearly half the book, which is a most important contribution to the study of carcinology, and will be extremely useful to all systematists.

The companion volume is "The Grapsoid Crabs of America," forming Bulletin 97 of the United States National Museum, 1918, and here is to be found an introduction serving for both volumes, which are to be followed by others. The collections in the United States National Museum, embracing many hundreds of specimens, form the basis of both bulletins.

We have in the present volume a handbook for the study of American spider crabs which will be indispensable to workers in all countries. Some of these crabs have an extremely wide range of distribution; such are *Hyas araneus* and *Hyas coarcticus*, aptly termed "toad crabs," both of which are common on British coasts. *Hyas coarcticus*, which was originally described by Leach from British seas, is shown to have also a wide vertical range, extending from low water to (exceptionally) 906 fathoms.

The love of spider crabs for decoration is remarkable, and although in a work of this kind there is no room for details as to habits, still much may be learnt from it as to habitat and adaptation. Whether the animals actually decorate themselves with foreign substances or, without using them, are so like their environment that decoration is unnecessary, they are all so perfectly adapted to their surroundings that even in dead specimens one can usually recognise the kind of ground on which they live. The members of the Majidæ are the most important of the "masking crabs," but even among these there are some which do not cover their bodies with extraneous matter. Thus we have the bright red *Thoe puella* in the fringing shallows living on broken pieces of coral which have portions of sponge scattered over them of a similar colour to the crab; and the hairy *Mithrax verrucosus*—the hiding-place of which is in rocky holes covered with madrepores—which only comes out to feed at night. In the smaller family, Parthenopidæ, there are *Heterocrypta granulata*, the "pentagon crab," living on shingly bottom, bearing a striking resemblance to a freshly broken chip or flake of stone, and *Parthenope serrata*, which lives in the sand in shallow water with only the rostrum, eyes, and afferent apertures exposed, these apertures being situated between the base of the finger and the margin of the orbit.

There are very good diagrams showing the nomenclature of the parts as used in the monograph, and the descriptions of the crabs and the keys are all clear and easy to understand.

University and Educational Intelligence.

ABERDEEN.—Ordinances for the establishment of chairs in forestry and bacteriology have been approved of by Order in Council.

The Right Rev. E. W. Barnes, Bishop of Birmingham, has been appointed Gifford Lecturer for the period 1926–8.

CAMBRIDGE.—Mr. G. E Briggs, fellow of St. John's College, has been reappointed as demonstrator in plant physiology. Mr. Briggs has in the past done effective research on carbon assimilation and growth.

The Royal Commission has issued amended regulations governing the initial appointments to be made under the new statutes.

Certain amendments to the regulations of the mechanical sciences tripos have been brought forward. The proposed changes are chiefly concerned with the regrouping and amendment of the "B" (advanced) papers, the special function of which is to grade the candidates.

The local nominees to the first committee of management of the new Polar Institute consist of the present Vice-Chancellor, and three antarctic explorers—Messrs. Debenham, Priestley, and Wordie. The Council of the Royal Geographical Society has nominated Dr. H. R. Mill as its representative.

A Gordon Wigan prize of 30*l.* has been awarded to Mr. F. H. Constable, fellow of St. John's College, for chemical research on "The Nature of Catalytic Action."

ST. ANDREWS.—The degree of D.Sc. has been conferred on Mr. James Forrest, lecturer in natural philosophy, University College, Dundee, for a thesis entitled "Magnetic Quality in Crystals; Part I., Magnetic Discrimination of Molecular Lattices; Part II., Stability of Molecular Lattices."

STERLING Fellowships for Research in the Humanistic Studies and the Natural Sciences at Yale University Graduate School have been established by a gift of 1,000,000 dollars from the trustees of the estate of the late John W. Sterling to stimulate scholarship and advanced research in all fields of knowledge. They are divided into two general classes: Research or Senior Fellowships, candidates for which must be of the standing of the Ph.D. degree; and Junior Fellowships, candidates for which must be well advanced in their work towards the Ph.D. degree. The annual stipends of the former range from 200*l.* to 500*l* or more, dependent upon the character of the proposed investigation, and of the latter from 200*l.* to 300*l.* The fellowships are open equally to graduates of Yale University and other approved colleges and universities. Applications for the fellowships should be addressed to the Dean of the Graduate School of Yale University, New Haven, Connecticut, for Junior Fellowships, by March 1, and for the Senior Fellowships by April 1.

THE December number of the *University Bulletin* of the Association of University Teachers contains an article by Dr. Alex Hill, of the Universities

---

[1] Smithsonian Institution: United States National Museum. Bulletin 129: "The Spider Crabs of America." By Mary J. Rathbun. Pp. xx+613 +283 plates. (Washington: Government Printing Office, 1925.) 2 dollars.

Bureau of the British Empire, on the promotion of "Interchange" of university teachers and students. By this phrase is meant temporary migration or short visits by teachers and students from the universities of Great Britain to those of another country for study, research, or teaching. The article traces the growth of the movement and its connexion with the growth of specialisation among universities from the year 1903, when, at a conference of universities, Lord Bryce pointed out that special opportunities of studying mining, forestry, and other branches of applied science were offered by the universities in the overseas dominions. The migration of British graduates to U.S.A. has received a substantial impetus in the past few years through the establishment of fellowships financed from America—especially the Commonwealth Fund fellowships founded last year. As regards migration of teachers, the article indicates that while the system established in many American universities of granting "Sabbatical" leave—furlough for an academic year after six years of service as professor—coupled with grants by the Institute of International Education of travelling allowances, makes the migration of American professors to Europe comparatively easy, the absence of any corresponding system in universities in Great Britain stands in the way of further development of migration by their professors, though it does not prevent them from paying visits of a few days' duration to continental universities. The faith of our universities in the benefits of interchange of professors has not yet availed to make them adopt the principle of the Sabbatical leave, even to the extent of announcing their willingness to grant such leave in the event of funds being provided to meet the expense involved.

THE prospectus for the year 1926–27 of the Imperial College of Tropical Agriculture, Trinidad, embodies a new feature in the form of the Principal's report, and a register of present and past students of the College has been inserted. The College has entered upon a new phase as the new buildings, the foundation of which was laid in January 1924, have now been opened by the Governor of Trinidad, and are in use. The Principal's report covers the academic year 1924–1925, the third year in the life of the College, and the first year of the term of office of the new principal, Dr. H. Martin Leake. The report indicates steady and useful progress both in the number of advanced and diploma students and in the amount and character of the research and investigation work that has been carried on. Full details of the courses of study in agriculture, botany, chemistry and soil science, economics, mycology, tropical sanitation and hygiene, veterinary science and zoology and entomology are given, and it will be seen that full provision is made to enable students to gain a very sound knowledge of tropical agriculture in all its branches. Reference is made to a hostel which is to be provided for students as soon as possible. A hostel will be needed all the more now that the Colonial Office has arranged to send students, under the Milner Scholarship Scheme, for a year's training in tropical agriculture before they take up their appointments in one of the Colonial agricultural departments. Though the importance of a hostel is fully realised by the governing body, funds, we understand, are not yet available for the purpose, and it is very desirable that Government and private benefactions should be made towards this very essential need of the College. The Imperial College has, we feel sure, so great a future before it that we commend the institution to the notice of all those who take an interest in the agricultural development of British Colonies.

Contemporary Birthdays.

January 29, 1845. Sir Robert Elliott-Cooper, K.C.B., Past. Pres. Inst.C.E.

January 30, 1851. Dr. Henry Ogg Forbes, F.R.G.S.

January 31, 1868. Prof. Theodore W. Richards, For. Mem. R.S.

Sir ROBERT ELLIOT-COOPER, born at Leeds, was educated there at the Grammar School, the headmaster of which at the time was Dr. (afterwards Bishop) Barry. Sir Robert's engineering pupilage began with the firm of Messrs. John Fraser of Leeds. Fifty years ago he settled in London to take up professional work. In 1912 he succeeded Prof. Unwin, F.R.S., as president of the Institution of Civil Engineers. His inaugural address dealt at length with the railways and works of the civil engineer in the overseas Dominions, the Crown Colonies, and the protectorates of the British Empire, many valuable statistics being brought together. During the War, Sir Robert was chairman of the War Office Committee of the Institution of Civil Engineers. He is a member of the executive committee of the National Physical Laboratory. It is interesting to note that Sir Robert's grandfather, when a young naval officer, sailed with Capt. Cook round the world, and was present at the discovery of Australia.

Dr. H. O. FORBES, traveller, anthropologist, museum curator, was born at Aberdeen. Educated at the city's grammar school, he proceeded to the Universities of Aberdeen and Edinburgh. He is LL.D. of the former. So far back as 1878, Dr. Forbes was exploring in Keeling Islands, Java, Sumatra and Timor, work which led to other undertakings in scarcely known lands. In 1885 he was chief of an expedition to explore Mount Owen Stanley, New Guinea. Director of the Canterbury Museum, New Zealand, 1890–93, he afterwards became Director of Museums to the Corporation of Liverpool. In various capacities he has proved a staunch helper to the British Association. Among many early memoirs, Dr. Forbes is the author of "On the Contrivances for ensuring Self-fertilisation in some Tropical Orchids"; "The Chatham Islands: their Relation to a former Southern Continent."

Prof. T. W. RICHARDS, Nobel laureate in chemistry, was born at Germantown, Pennsylvania. Son of a painter of landscapes and marine subjects, his mother was the author of various poetical works. She it was who conducted in the home Richards's early education, which was continued at Haverford College and Harvard University. Afterwards there was intensive study at Göttingen, Leipzig and Dresden Technical School. Becoming an assistant at Harvard in 1889, Prof. Richards is now Erving professor of chemistry and Director of the Wolcott Gibbs Memorial Laboratory, Harvard, U.S.A. The Nobel prize in chemistry for 1914 was allotted to him in recognition of his exact determinations of the atomic weights of a large number of the chemical elements. At the laureate ceremonies, Prof. H. G. Söderbaum, of Stockholm, said: "The work he has accomplished as a reformer of chemical methods and practices is by no means the least insignificant phase of his achievements." The Royal Society's Davy Medal had been awarded earlier. So too, the Chemical Society's Faraday Medal, given on the occasion of the Faraday lecture. "The solution," said Richards, "of the cosmic riddle is of the greatest importance to humanity, because only through a complete understanding of his own structure and that of his environment can man obtain control of the necessary conditions of his existence."

Early Science at Oxford.

February 1, 1683–4. Mr. Desmasters gave us an account of some experiments lately made by him, concerning ye expansion of Water frozen; he observed, that a cylindricall tube of ¼ of an inch diameter, being filled with water, to ye height of 2 inches, and set to freeze, in a mixture of snow, and salt; ye water, when perfectly frozen, appeared $\frac{1}{11}$ of an Inch above ye marke it stood at before ye freezing began. Another cylindricall tube of almost an inch diameter, being filled with water to ye height of 6 inches, and set to freeze as before; ye water in freezing rose $\frac{3}{8}$ of an inch; he observ'd farther, that when ye water thus set in snow and salt, began to freeze, a great number of small bubbles rose continually from ye bottom for some time. Mr. Ballard has observed of late, that half a pint of water frozen, lost ʒij—ʒij—grviij of ye weight it was of, before ye freezing; this experiment he tried a 2d time; ye success was much ye same, as at ye first. It was then queried, whether water, out of which ye air is pumpt, will rise in ye middle in the time of its freezing? and whether boiled water rises in freezing? Dr. Plot, and Mr. Ballard, undertook to trye these experiments.

Mr. Ballard gave an account of his success in trying some of Mr. Chamar's Experiments; whereas amongst other things Mr. Chamar says that Iron touched will loose its vertue, by being filed; Mr. Ballard says, this is true, if ye Iron be filed *all over*, not otherwise. Dr. Plot shewed some of ye Turkish *Rusma*, and *Alcanna*, which he lately received from Mr. Smith, Student of Christ Church, and chaplain to ye Factory at Smyrna, who wrote of ye use of ye Rusma, the *Alcanna* is ye leaf of a plant, dried, and powdered; which, when steept a night in wine, will die ye nails red; and I suppose ye gentleman means Smyrna, or such like wine, for (as Dr. Plot tells us) it will not succeed with Canary, or Claret.

Dr. Plot then proposed, and it was ordered by ye Society, that an exact account of ye weather should be kept, either according to Mr. Lister's, or some such compendious, method; and that at ye end of this, and other years, ye account of ye weather of preceding years, one or more, should be printed with an almanac for ye year to come.

February 1, 1686–7. An account was communicated by Mr. Musgrave of a way to preserve beef for three quarters of a year, and then half a year more after roasting.—An account of two high tides at London Jan. ye 28th, one 5 hours after the other.—An account of several extraordinary productions of a fœtus, bred out of a cat and a rat; the cat being the dam. This fœtus is now to be seen at the Earl of Abingdon's, as likewise a *Hirco-cervus* bred of a goat and a deer at ye same place. An account of several productions of a colour different from that of their species: e.g. of a white Ouzle or Black-bird, of white mice at one Mr. Tillyard's, an Apothecary in Oxford; of white Woodcocks, Partridges, Pheasants, &c. seen by several of the Society.

February 2, 1685–6. A letter from Mr. Nicholson to Sir Wm. Dugdale concerning the Runic Inscription at Bridekirk was comunicated by Dr. Plot.—A Paper of Dr. Papin's explaining ye use of his Water Engine was also read.

February 3, 1684–5. Two letters from Mr. Cuningham, of St. Leonards College, were read: the latter of these mentions a way used in Scotland for ye cleansing mines of noxious vapors; the miners carry down a candle, in a dark lantern, covered with a wet cloth; then, lying flat on their faces, they, in that posture, kindle, and maintain a fire, which carryes off ye vapors, without injuring ye miners.

Societies and Academies.

LONDON.

Royal Society, January 21.—**R. E. Gibbs**: Structure of α quartz. Investigations on quartz have shown that symmetry and X-ray data enable only partial definition of structure. Intensity measurements and general physical properties of the material must also be studied. Oxygen atoms occupy positions *c*/9 above and below the silicon atoms. Only a small structural change accompanies the transition from β to α quartz, but still the tetrahedral character of β quartz is lost. The structure proposed assumes the crystal to be non-molecular and the oxygen to occupy basal planes as noted above. The silicon atoms seem to move about 0·3 Å.U. from their β-positions.—**N. K. Adam** and **G. Jessop**: The structure of thin films, Pt. vii. Critical evaporation phenomena at low pressures By means of a new apparatus, measurements of the surface pressure of monomolecular films have been made at room temperature, down to 0·01 dyne per cm. At areas greater than about 5000 sq. Å.U. per molecule, the pressures exerted by films of insoluble fatty substances tend to a value within 25 per cent. of that given by the equation $Fa = RT$, R having the same value as in a perfect gas. The divergences from the theoretical values are probably within experimental error. Between 100 and 5000 sq. Å.U. the pressure-area isothermals closely resemble those for liquid and vapour in three dimensions. Expanded films are analogous to liquids, *not* vapours, and there is considerable cohesion between the molecules in them.—**H. J. Gough, D. Hanson** and **S. J. Wright**: The behaviour of single crystals of aluminium under static and repeated stresses.—**C. H. M. Jenkins**. The determination of the vapour tensions of mercury, cadmium, and zinc by a modified manometric method. The apparatus consists of a specially designed manometer, using the material under determination as the observed liquid in this gauge; it can be inserted in a 3-inch diameter electric tube furnace. The pressure on the apparatus is regulated by means of nitrogen, the pressure of which is measured on an independent barometer. The vapour pressure of the liquid is measured over a free surface in the closed end of the manometer by alterations in the pressure of the nitrogen to bring both liquid surfaces in this gauge level. The apparatus is similar to the letter V in shape. One extremity is closed; the other opens into a long straight column bent at right angles to it. Into this column specially shaped pieces are inserted, transforming it into a reflux condenser, which counteracts the diffusion of the nitrogen into the vapour. Values have been obtained for the vapour tensions of mercury, cadmium, and zinc over the range of pressure from 15 to 1500 mm. The boiling-points (760 mm) have been found to be 357°, 767° and 906° C. respectively.—**W. Barlow**: The configuration of the carbon atom and the geometrical relations of this configuration to those of other atoms, as evidenced in the chemical and crystallographic structures of organic chemistry. Pt. i.—**Ursula Andrewes, Ann C. Davies** and **F. Horton**: The soft X-ray absorption limits of certain elements. Investigations have been made of the voltages corresponding to critical values of electron energy associated with some of the longer wave-length absorption stages of seven successive elements, chromium, manganese, iron, cobalt, nickel, copper and zinc. The generally accepted value of an absorption limit, obtained by spectroscopic methods, corresponds not to ionisation of the atom by the detachment from it of an electron in the sub-group concerned, but to the transportation of the electron from the sub-group to the periphery of the atom, *i.e.* to the levels of the most loosely bound electrons The values obtained in this investigation are associated with absorption of energy by electrons in the M sub-groups, the several values obtained for each element being attributed to selective absorption stages, and not to actual ionisation of the atom.—W. L. **Bragg** and G. B. **Brown** · The crystalline structure of chrysoberyl. Chrysoberyl, $BeAl_2O_4$, is analogous in chemical composition to the spinel group of minerals $R''R_2'''O_4$. It is entirely different in its crystalline form, being orthorhombic, whereas the spinels are cubic. It may be supposed that the oxygen ions occupy the greater part of the volume in the crystal, and the metal ions are placed in the interstices between a close-packed assemblage of oxygen ions. A comparison of BeO, Al_2O_3, $BeAl_2O_4$, shows that in each case the oxygen atoms are very nearly in a close-packed hexagonal arrangement and that the distances between atomic centres are almost identical from the three crystals, being about 2·7 Å.U. Each aluminium atom in Al_2O_3 and $BeAl_2O_4$ occupies a position between six oxygen atoms. The hexagonal close-packed lattice can be referred to orthorhombic axes with ratios $\sqrt{2/3} : 1 : \sqrt{3/3}$.—H. G. **Telling**: On a set of quartic surfaces in space of four dimensions, and a certain involutory transformation. Each of the surfaces in four dimensions may be generated by taking three arbitrary skew lines and two arbitrary points, drawing a plane through each of the points to meet the three lines, and then finding the locus of the intersection of the plane through the first point with the plane through the second point. The geometry of the surface then suggests the consideration of, in all, fifteen lines, of which that joining the two given points is one; and then passing through an arbitrary given point of the space, there are fifteen such surfaces, one associated with each of the lines. The paper is concerned with determining the intersection of any two of these fifteen surfaces.—L. F. **Richardson**: Atmospheric diffusion shown on a distance-neighbour graph. The atmospheric diffusivity in Fick's equation has been found by various investigators to increase from 0·2 cm.^{2} sec.$^{-1}$ to 10^{11} cm.^{2} sec.$^{-1}$ as the size of the cluster of diffusing particles increases from 10^{-2} to 10^8 cm. The effect is due to eddies of many sizes acting together. There is apparently no way of modifying Fick's equation in order to describe this phenomenon. But a new mathematical method is here developed, in which, instead of thinking about concentration as a function of position, we think about q, the mean number of neighbours per length, as a function of l, their distance apart This gives a rough average value 0·6 $l^{4/3}$ cm.^{2} sec.$^{-1}$ for the atmosphere, when l lies between 1 metre and 10 km.—T. **Alty**: Some phenomena occurring at the surface of bubbles in water. The surface tensions of water in contact with various gases are compared by the drop-weight method. The weight of a bubble is independent of the gas used if the rate of flow is slow enough. To examine a new water surface, the rate of flow is increased until several bubbles emerge per second. When flowing from the same capillary, the gases form bubbles the volumes of which can be arranged in decreasing order as follows: argon, nitrogen, oxygen, ozone, hydrogen, nitric oxide, carbon dioxide. These differences are related to the adsorbability of the gases.—A. L. M. **Sowerby** and S. **Barratt**: The line absorption spectra of the alkali metals. The alkali metals are all able to absorb the lines of the combination series *1s-md*, contrary to the Selection Principle. The cæsium series of this type has been observed for the first time. The absorption of this series by potassium is uninfluenced by the presence of argon at two atmospheres pressure. It is estimated that 12,000 times as many atoms can absorb the first member of the principal series of potassium and rubidium as can absorb the line *1s-3d*, the ratio being the same for the two metals. The "atomic extinction coefficients" of the different alkali metals are approximately the same for corresponding lines.—A. M. **Tyndall** and G. C. **Grindley**: The mobility of ions in air. Pts. i. and ii. The improved method of measuring mobility depends on producing ions by flashes of α-rays subjected to a special alternating field. The effect of water vapour is to cause fall of mobility of fully formed negative ions down to a value 1·6 in saturated air. Positive ions of two types were found—initial and final. The mobility of the initial type is indistinguishable from that of the negative and is similarly affected by water vapour. Water vapour has a retarding influence on rate of transformation into final ions. In ordinary dry air much transformation occurs within 0·007 sec. of birth, but in wet air the ions nearly all remain in the initial stage at double this age.—W. **Jevons**: A band spectrum of tin monochloride exhibiting isotope effects. The spectrum of the uncondensed discharge through $SnCl_4$ vapour comprises a continuous spectrum between λ 4900 and λ 3950, and a hitherto unrecorded band spectrum consisting of two distinct sets of bands occupying the regions λ 3910 – λ 3486 and λ 3405 – λ 2830 respectively. Each set is attributed to a chloride of tin. The bands in the more refrangible set constitute two systems α and β of the normal Deslandres type. If they be ascribed to $SnCl^{35}$, a few additional bands in the same region are attributable to $SnCl^{37}$. There is also some indication of the tin isotope effect. The less refrangible set consists of several groups, each containing a few close bands degraded towards the red. Too little is known of these bands to say whether they are emitted by SnCl or by a polyatomic chloride.—J. H. **Andrew**, M. S. **Fisher** and J. M. **Robertson**: Some physical properties of steel and their determination. Methods of measuring electrical resistance, electrode potential, and continuous change of resistance during tempering, are described. The change from martensite to granular pearlite is gradual and only proceeds to a certain stage at each temperature. Martensite is not formed during tempering at constant temperature, but results from the decomposition of austenite during cooling from the tempering temperature. The rate of tempering of martensite is not affected by the addition of moderate amounts of special elements. Austenite tempers more slowly, and its rate of tempering is considerably reduced by addition of special elements.—N. K. **Adam** and G. **Jessop**: Note on the spreading of solids on water surfaces. Cary and Rideal's observations on the spreading of myristic acid on water have been continued down to very low compressions. A small pressure, that of the "gaseous" state of the film, is set up immediately the crystal touches the surface, and the "two-dimensional vapour pressure" very soon afterwards.

Royal Microscopical Society, December 16.—F. I. G. **Rawlins**: The theory of dimensions in microscopy. The fundamental quantities of interest to the microscopist, such as the power of a lens, curvature, numerical aperture, resolution, convergence, are considered from a dimensional point of view. A number of magnitudes in common use for interference work are discussed dimensionally, and the importance of the inclusion of the appropriate constants of proportionality when dealing with geometrical properties is stressed.

Edinburgh.

Royal Society, January 11.—A. Anstruther **Lawson**: The origin of endemism. The vast continental, insular flora of Australia, with 70 per cent. of its species and 30 per cent. of its genera endemic, is perhaps the most favourable of all fields for the study of endemism. From a study of their habits, habitat, foliage, variability, great profusion of flowers, sterility of flowers, and low percentage of seed set of the main endemic types, which is so characteristic, it seems at least the majority are hybrids Hybridisation seems to occur in the Australian flora wherever possible, and the possibilities are quite general. The endemic flora had its origin as hybrid mutations derived in the first place from non-endemic types. Hybrid mutations—followed by natural selection—has been the main determining factor and influence in the evolution of the Australian flora. Such conclusions are directly opposed to the theory of De Vries and to the Morgan School in America.—G. Gordon **Harrower**: A study of Ho-kien and Tamil skulls. The Ho-kien, native of the Chinese province of Foo-kien, differs in certain particulars from that of the northern Chinese, and represents a more or less pure strain of the indigenous Mongolian type which preceded the Chinese in south-eastern Asia. Comparisons reveal certain affinities with one type of Tibetan skull—a point of interest in connexion with the question of origins. The sample of Tamil skulls collected represents one group of the indigenous Dravidians of southern India. The skull is relatively long and narrow, and is high; the face is low and relatively broad, and the nasal aperture is only moderately broad in proportion to the height. The skull differs in several particulars from European skulls of the same class, notably in the smaller expansion of the occiput; it shows no admixture with the intrusive Aryan element.—D. A. **Fairweather**: Electrosynthesis in the series of normal dibasic acids. Three new acids of this series have been synthesised by Crum Brown and Walker's electrosynthetic method, namely, those with 20, 24 and 28 methylene groups.—C. C. **Miller**: The slow oxidation of phosphorus trioxide Pt. i. The action of water vapour on phosphorus trioxide. The oxidation of phosphorus trioxide to pentoxide by oxygen at low temperatures (25°) is accompanied by luminescence, and only takes place in the presence of water vapour, the pressure of which need only be very low. In the absence of oxygen it was found that at 25°, under certain conditions, comparatively large quantities of gaseous and liquid phosphuretted hydrogen were produced, which may play a part in the oxidation when oxygen is present.—E. T. **Copson**: Partial differential equations and the calculus of variations. The conditions under which a linear partial differential quation of the second order may be derived by nnulling the variation of an integral are determined. The self-adjoint equation is shown to be a particular case. Systems of equations are also discussed.

Rome.

Royal Academy of the Lincei, November 15.—T. **evi-Civita**: Gravitational movements in one dimension.—G. **Armellini**: Theory of the flying shadows in solar eclipses. The shadow bands moving in front of, and parallel to, the lunar shadow during total solar eclipses are regarded as an ordinary diffraction phenomenon.—F. **Zambonini** and G. **Carobbi**: Double sulphates of rare earth and alkali metals (iv.). Double sulphates of neodymium and sodium. Compounds containing $Nd_2(SO_4)_3$, Na_2SO_4, and H_2O in the respective molecular proportions 1:1:2, 4:5:8, 3:4:6, and 2:3:5 have been obtained as pale violet-red crystals.—F. **Zambonini** and R. G. **Levi**: Isomorphism of molybdates of the rare earth metals with those of calcium, strontium, barium, and lead (iv.). Structure of the molybdates of lanthanum, cerium, praseodymium, neodymium, and samarium.—L. **Sabbatani**: Pharmacological action of iron with double and complex salts.—S. **Franchi**: Geological problems in the Franco-Italian Alps.—L. A. **Herrera**: Imitation of cell-division and spore-germination by means of calcium fluosilicate.—G. **Tizzoni**, E. **Centanni**, and G. **De Angelis**: Modifications produced by radium in the substance of the cancer tumour of the young rat, and its transformation into a curative vaccine.—W. **Blaschke**: Cyclic systems of curves on a surface.—Antonio **Signorini**: A theorem of existence and singularity in the statics of materials exhibiting low resistance to tension.—Bruno **Finzi**: Potential laminary liquid motions on developable surfaces.—Rita **Brunetti**: Relative magnitude of atoms and ions.—A. **Pontremoli**: A characteristic experiment in electric or magnetic double refraction.—G. R. **Levi**: The varieties of thorium oxide and their catalytic action in the dehydration of alcohol. The so-called meta-oxide of thorium is crystalline and identical with the normal oxide, whereas the thorium hydroxide usually obtained is amorphous and undergoes transformation into an amorphous oxide stable at temperatures higher than 300°. The catalytic influence of the oxide on the dehydration of alcohol is not affected by its crystalline or amorphous character.—Raoul **Poggi**: Some derivatives of toluene.—C. **Sandonnini**: Actions in the presence of carbon.—Paolo **Principi**: Observations on the geology of the upper and middle valleys of Savio.—Beatrice **Torelli**: The significance of heterochromosomes.—Umberto **D'Ancona**: Influence of salt solutions on the resistance of young eels to fasting.—Remo **Grandori**: Studies on the blastokinesis of insects.

Washington, D.C.

National Academy of Sciences (*Proc.*, Vol. 11, No. 12, December 1925).—George H. **Shull**: The third linkage group in Œnothera. A mutation called "old-gold" (*vetaurea*) found in *Œ. Lamarckiana* is the first discovered factor of a third linkage group. Another factor of the same group, "double" flowers (called mutant *supplena*), is now announced.—Horace W. **Feldman**: Fertility of the rat, *Mus norvegicus*. Fertility in the Norway rat is generally dependent on the vigour of the female. The size of litter increases to a maximum at the age of 150-179 days and decreases afterwards to a minimum, due apparently to the decrease of general vigour with age. Inbreeding increased the frequency of still-births. Seasonal fluctuations occurred: litters showed an average maximum (7·3 young) in June, decreasing to a low point (5·2 young) in October and increasing again in November and December.—Tracy Yerkes **Thomas**: Invariants of relative quadratic differential forms.—R. L. **Wilder**: A property which characterises continuous curves. A continuous curve is a bounded continuum connected *im kleinen*, and such curves are characterised by being "normally connected."—Carl **Barus**: Telephonic coupling of acoustic and electrical oscillations evidenced by the pinhole probe.—J. C. **Slater**: Interpretation of the hydrogen and helium spectra. Pauli has suggested that the double levels in atoms having one valence electron have some connexion with a duality in the quantum laws. This would lead to resemblances between the spectra of hydrogen and helium and those of the alkalis and alkaline earths respectively. Evidence of this is adduced.—J. G. **Winans**: Radiation emitted by optically excited zinc vapour. Zinc vapour in a quartz "resonance" tube was illuminated by a water-cooled zinc arc maintained in a quartz tube. Thirteen lines were detected in the spectrum observed and accounted for; in addition, four bands appear which are more intense relative to the lines in the optically excited radiation than in that from the zinc arc. Mercury as an impurity in the zinc vapour gives evidence of "impact fluorescence."—Ernest Merritt: On contact rectification by metallic germanium. Rectifying properties were observed, the contact being stable, and the behaviour at different points fairly uniform. Making contact with bismuth gives anomalous results. Platinum was also used and the temperature raised. The resistance of the contact becomes much smaller, and at 220° C. it was the same in both directions through the contact. On cooling, the resistance remained greater than it was before heating, due apparently to a highly resistant film of oxide.—Henry Fairfield Osborn: The origin of species (ii.). Further detailed statements are made on some of the nine bio-mechanical principles of adaptation enunciated in an earlier paper (NATURE, June 13, 1925, p. 925, and June 20, 1925, p. 961).—Raymond Pearl: Vital statistics of the National Academy of Sciences. (i.) Age at election. The original membership was of high average age; of the 48 charter members, only 4 were less than 38 years old. During the period 1864–83, the mean age at election was 44·47 years; for 1884–1904, it increased to 46·54 years; and for 1905–1924, another four years were added. Of the 213 elected during this last period, only 8 were less than 38 years old. These figures show the same tendency as the statistics of the Royal Society. (ii.) Elections of young men. 43 persons, including 2 charter members, were less than 37 years old at election. Of these, 30 worked at the physical and 12 at the biological sciences. The youngest man elected was the astronomer, E. C. Pickering (26·8 years), and the next youngest, the engineer, Fairman Roger, charter member (29·3 years). (iii.) Mortality. At 40 years of age, members of the Academy have a mean after lifetime more than five years greater than that of urban white males of the United States, and some increased expectation is maintained up to the age of 85 years. This might be expected, since they belong to the occupational groups giving superior risks from the life insurance viewpoint. (iv.) The present limitation to total membership and other matters. With living membership of 221, 15 elections, and an average of 8 deaths annually, the Academy will reach its limit of 250 members in 1929; thereafter, the mortality will allow of the election of 6 to 8 members a year. The present mean age of members is 60·74±0·47 years; their mean duration of service is 12·17±0·48 years, and that of members who have died was 19·57±0·60 years.—Marston Taylor Bogert and Hugh Blake Corbitt: Researches on thiazoles (x). The synthesis of some 2-phenyl-benzothiazole arsonic acids. These compounds are important therapeutically, for one of them has a greater action on *Tr. equiperdum* and greater toxicity for white rats than the corresponding benzene compound, but there was no evidence of any effect on the nervous system such as is frequently caused by penta-valent arsenic compounds.—S. C. Lind: The origin of terrestrial helium and its association with other gases. Helium is very generally distributed in natural gases, but in widely different concentrations (maximum nearly 4 per cent.). It is not confined to limited geological horizons, suggesting that its occurrence in quantity is due to prevention of leakage by a gas-seal, such as a capping of shale containing clay. A radioactive origin is favoured. It is always found with high though variable nitrogen content, possibly due to the action of the initial α-particle producing nitrogen and helium simultaneously, from some nitrogen compound in the parent mineral.

Diary of Societies.

SATURDAY, JANUARY 30.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—H. Balfour: The British Coracle or Skin-covered Boat, and its Affinities.

NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS (Associates and Students' Section) (at Neville Hall, Newcastle-upon-Tyne), at 3.—P. F. Hope: The Sinking of Monkton Shaft.

INSTITUTE OF METALS (North-East Coast Local Section) (jointly with Institution of British Foundrymen) (at Neville Hall, Newcastle-upon-Tyne), at 6.15.

MONDAY, FEBRUARY 1.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.—General Meeting.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. A. Edmunds: Pseudo-Hermaphroditism and Hypospadias and their Surgical Treatment.

SOCIETY OF ENGINEERS (at Geological Society), at 5.30.—G. O. Case: Presidential Address.

INSTITUTION OF ELECTRICAL ENGINEERS (Western Centre) (at Merchant Venturers' Technical College, Bristol), at 6.

ARISTOTELIAN SOCIETY (at University of London Club), at 8.—G. C. Field: Ancient Philosophy and Modern Science.

ROYAL SOCIETY OF ARTS, at 8.—H. P. Shapland: The Decoration of Furniture (Cantor Lecture) (3).

Society of Chemical Industry (London Section) (at Institution of Mechanical Engineers), at 8.—F. H. Carr: The Training of Chemists for Industry.

Royal Institute of British Architects, at 8.30.—Presidential Address to Students.

Royal Society of Medicine (Social Evening), at 9.30.—Dr. F. J. Poynton: The Part taken by Doctors in the Early Days of Aeronautics.

TUESDAY, February 2.

Imperial College Chemical Society (jointly with Royal College of Science Natural History Society and Royal College of Science Physical and Mathematical Society), at 5.—Prof. H. E. Armstrong: Chemical Change in General.

Royal Institution of Great Britain, at 5.15.—Dr. E. K. Rideal: Surface Action (1).

Manchester Geological and Mining Society (at the University, Manchester), at 6.—Sir Stopford Brunton: Mining in Canada with regard to Migration.

Institute of Marine Engineers, at 6.30.—S. S. Cook: High-efficiency Steam Installations for Ship Propulsion.

Institution of Electrical Engineers (North-Western Centre) (at Engineers' Club, Manchester), at 7.—E. V. Clarke: Power Factor and Tariff.

Royal Photographic Society of Great Britain (Pictorial Group), at 7.

Institution of Automobile Engineers (Coventry Graduates' Section) (at Broadgate Café, Coventry), at 7.15.—J. R. Harriott: Developments in Motor Cycle Design.

North-East Coast Institution of Engineers and Shipbuilders (Middlesbrough Branch) (at Cleveland Scientific and Technical Institution, Middlesbrough), at 7.30.—Capt. Rogers: Ships' Cargo Handling Appliances.

Röntgen Society (at British Institute of Radiology), at 8.15.—R. J. McCallum Tozer: A Gas Tube with Variable Penetrating Power.—M. A. Codd: A New Regulator for a Gas Tube.

Society of Chemical Industry (South Wales Section) (at Institute of Engineers, Cardiff).—W. J. U. Woolcock: Medicinal Fine Chemicals.

WEDNESDAY, February 3.

North of England Institute of Mining and Mechanical Engineers (at Neville Hall, Newcastle-upon-Tyne), at 3.—W. Ridley and others: Discussion on Power Production and Transmission.

Royal College of Surgeons of England, at 5.—Prof. J. E. Adams: The Surgery of the Jejunum.

Geological Society of London, at 5.30.—Prof. S. J. Shand: The Alkaline Rocks and Ring-Intrusions of Pilansberg (Transvaal) (Lecture).

Institution of Electrical Engineers (Wireless Section), at 6.—J. Hollingworth: The Propagation of Electric Waves.

Society of Public Analysts and other Analytical Chemists (Annual General Meeting) (at Chemical Society), at 8.—Dr. L. H. Lampitt and E. B. Hughes: The Determination of Copper in Vegetables.—Dr. H. E. Cox: Arsenic in Apples.—A. J. Berry:—The Titration of Thallous Salts by Potassium Iodate.—C. H. Wright: The Hot Springs at Nasavusavu.

Royal Society of Arts, at 8.—Sir John Russell: Investigations in Agricultural Science at Rothamsted.

Entomological Society of London, at 8.—G. Fox-Wilson: The Insect Visitors to Slime-Flux.

THURSDAY, February 4.

Royal Society, at 4.30.—Prof. W. A. Bone and R. Quarendon: Researches on the Chemistry of Coal. Part IV.—G. M. B. Dobson and D. N. Harrison: Measurements of the Amount of Ozone in the Earth's Atmosphere and its Relation to other Geophysical Conditions.—Dr. C. Chree: Atmospheric Ozone and Terrestrial Magnetism.—Dr. J. S. Owens: Condensation of Water from the Air upon Hygroscopic Crystals.—*To be read in title only*:—Prof. T. H. Havelock: Wave Resistance: Some Cases of Unsymmetrical Forms.—Dr. H. Jeffreys: On the Formation of Water Waves by Wind.—Prof. G. T. Morgan, W. J. Hickinbottom, and T. V. Barker: Stereoisomeric Diaryl-$\beta\gamma$-Diamino-N-Butanes.—Prof. G. T. Morgan and G. R. Davies: Antimonial Analogues of the Cacodyl Series.—Prof. G. T. Morgan and V. E. Yarsley: Dimethylstibine Cyanide, an Analogue of Cacodyl Cyanide.

Linnean Society of London, at 5.—C. C. A. Monro: Polychæta of the *Alert* Expedition;—Conclusion.—Dr. C. C. Hurst: On the Nature and Origin of Species in Rosa.

Royal Institution of Great Britain, at 5.15.—Dr. J. L. Myres: Who were the Greeks? (1).

Institution of Electrical Engineers, at 6.—E. V. Clark: Power Factor and Tariff.—H. W. Dorey: Power Factor Improvement.

Institution of Automobile Engineers (at Royal Society of Arts), at 7.—C. L. Lawrence: American Aeronautical Engine Practice.

Society of Chemical Industry (Bristol Section) (at Bristol University), at 7.30.—Dr. A. Parker: The Smokeless Fuel Problem.

Institution of Structural Engineers, at 7.30.—W. J. H. Leverton: The Æsthetic Treatment of Concrete.

Chemical Society, at 8.—F. G. Mann and Sir William J. Pope: (*a*) The Complex Salts of $\beta\beta'\beta''$-triaminotriethylamine with Nickel and Palladium; (*b*) $\gamma\gamma'\gamma''$-Triaminotripropylamine and its Complex Compounds with Nickel.—P. L. Robinson and H. C. Smith: A Comparison of the Atomic Weight of Silicon from Different Sources.

Institution of Mechanical Engineers (Glasgow Branch) (at Glasgow), T. B. Mackenzie: Modern Steel Works Plant for Boiler and Ship Plates Manufacture.

FRIDAY, February 5.

Royal Sanitary Institute (at Town Hall, Bradford), at 2.—Dr. J. R. Kaye, Dr. Helen M. Gall, Dr. Charlotte A. Douglas, Katherine Gamgee, and others: Discussion on Child Welfare Centres and their Adjuncts.—At 5.—F. Marsden, F. White, and others: Discussion on Town Planning and Improvement Areas.

Royal Astronomical Society (Geophysical Discussion), at 5.—R. D. Oldham and Prof. Turner: The Depths of Earthquake Foci in Relation to Distribution of Intensity on the Surface. Sir Gilbert Walker in the chair.

Royal College of Surgeons of England, at 5.—Prof. M. Woodman: Malignant Disease of the Œsophagus.

Society of Chemical Industry (Manchester Section) (at 16 St. Mary's Parsonage, Manchester), at 7.—A. Beavell: Fluid Heat Transmission for High Temperatures in Industrial Processes.

Royal Photographic Society of Great Britain, at 7.—S. L. Bevestaff: Thoughts which occur to me.

Photomicrographic Society (at 4 Fetter Lane), at 7.—F. A. Buddock: Photomicrography applied to Metallurgy.

Society of Chemical Industry (South Wales Section) (at Swansea Technical College), at 7.30.—C. A. Seyler: Micro-structure of Coal.

Junior Institution of Engineers, at 7.30.—Question and Discussion Evening.

North-East Coast Institution of Engineers and Shipbuilders (Middlesbrough Branch, Graduate Section) (at Middlesbrough), at 7.30.—E. Clarke: Launching.

Geologists' Association (at University College) (Annual General Meeting), at 8.—H. Dewey: Studies in Danish Geology (Presidential Address).

Royal Institution of Great Britain, at 9.—Prof. G. Gordon: Shakespeare's English.

SATURDAY, February 6.

Association of Women Science Teachers (Annual General Meeting) (at St. Paul's Girls' School), at 10.30 A.M.—Educational Films, chiefly Scientific, shown by the Visual Education Society.—At 2.30.—Miss Coward: The Teaching of Hygiene in Schools; Short Papers on the same subject.

Society of Chemical Industry (South Wales Section) (jointly with Institute of Chemistry and Wales and Monmouthshire Junior Gas Association) (at University College, Singleton Park, Swansea), at 2.30.—C. A. Seyler: The Microscopy of Coal.

Royal Institution of Great Britain, at 3.—Sir Walford Davies: The Triad and the Perfect Fourth (1).

Gilbert White Fellowship (at 6 Queen Square, W.C.1), at 3.—Miss L. E. Cheesman: Insect Collecting in the Society Islands.

PUBLIC LECTURES.

SATURDAY, January 30.

Horniman Museum (Forest Hill), at 3.30.—H. Harcourt: Glimpses of Indian Places and Peoples.

MONDAY, February 1.

University College, at 4.—Prof. A. V. Hill: The Physiology of Muscle. (Succeeding Lectures on February 8, 15, 22, March 1, 8.)—At 5.15.—Dr. R. W. Lunt: The Chemistry of Ionisation by Collision (Succeeding Lectures on February 8, 15, 22, March 1, 8.)—At 5.30.—Dr. A. S. Parkes: The Physiology of Reproduction. (Succeeding Lectures on February 8, 15, 22.)—At 5.30.—Prof. E. De Martonne Two French Geographical Regions: (1) Brittany; (2) The "Causses" of Southern France. (Succeeding Lecture on February 2.)

King's College, at 5.30.—Dr. F. A. P. Aveling: The Human Will (3) Post-Renaissance Views.

TUESDAY, February 2.

King's College, at 5.30.—Miss Hilda D. Oakeley: Philosophy an History (1). History in the Absolutist Philosophy.

University College, at 5.30.—Miss M. A. Murray: Primitive Cults in Ancient Egypt.

WEDNESDAY, February 3.

University College, at 5.30.—B. M. Headicar: The London Schoo of Economics Library, its Work and Methods.

THURSDAY, February 4.

University College, at 4.30.—Prof. E. G. Gardner: The Florentin Academies in the Renaissance.

King's College, at 5.—Dr. J. A. Hewitt: Metabolism of Carbohydrat and Fat. (Succeeding Lectures on February 11, 18, 25, March 4, 11.)

SATURDAY, February 6.

Horniman Museum (Forest Hill), at 3.30.—W. J. Perry: The Quest fo Gold and Pearls in Ancient Times.

Editorial and Publishing Offices:
MACMILLAN & CO., LTD.,
ST. MARTIN'S STREET, LONDON, W.C.2.

The Status of the Naval Engineer.

On November 20, 1925, the Admiralty issued a Fleet Order which, while to some extent affecting all branches of the Navy, has raised serious questions regarding the future status of the officers of the engineering branch. Hitherto there have been five branches in the service, but this order brought into being thirteen separate categories. Some of these, however, such as the dental branch, the schoolmaster branch, and the wardmaster branch, are but small sections of the personnel. The branch principally affected is the engineering branch, and the situation created by the order was felt to be so adverse to the best interests of the service that Lord Weir, Sir Charles Parsons, Sir John Thornycroft, and Sir Archibald Ross jointly addressed a letter to the press on the subject. This letter has been followed by other communications and articles, and on January 14 a deputation representing the Institutions of Civil Engineers, Mechanical Engineers, Naval Architects, and Electrical Engineers, and also the North-East Coast Institution of Engineers and Shipbuilders, waited upon the First Lord of the Admiralty (the Right Hon. W. C. Bridgeman) to place their views before him. So far no account of this deputation has been made public, but we can scarcely think that representations made by such a responsible body will be disregarded.

There have been engineers in the Navy now for more than a hundred years, and in the struggle of the engineer officers for adequate recognition there have been many memoranda, petitions, and deputations, but never before have the four founder engineering institutions taken so notable a step as that referred to, and their action can be taken as significant of the importance of the questions raised. It is therefore only right that the main points at issue should be made as clear as possible, so that whatever the results of the deputation, the whole position may be judged impartially.

It may, however, be said that no reasoned opinion on the engineering question can be formed without a knowledge of the past, and thus a few brief historical notes will be of use. Steam vessels appeared in the Navy so long ago as 1820. At first they were small dispatch vessels, and the engineers were mechanics of little or no education. By 1837 the steam frigate had been evolved, engines had become larger, and the engineers were given warrant rank. With the coming of the screw and its adoption in the old line-of-battleships, the steam department grew apace, and in 1847 engineer officers were raised to an equality with the masters and assistant masters who then comprised the navigating branch. Even at that time there was a scheme for training boys for naval engineering duties, but this did not amount to much, and when the Crimean War was in progress, recruits had to be sought for over a wide area. By the 'sixties the boys had become engineer students, who were taught in the Dockyard Schools, and some of these passed to the Royal School of Naval Architecture and Marine Engineering at South Kensington. The officers so trained were the best marine engineers of the day, but when they entered the service they found themselves subjected to all sorts of disabilities as to pay, half-pay, promotion, retirement, accommodation, and relative rank. It is not surprising to know that these unsatisfactory conditions led to great discontent.

A new and promising chapter was opened in 1875 with the appointment of a committee of three executive officers and two engineer officers, Admiral Cooper Key being chairman, to report on the best method of staffing the engine-rooms of the Fleet. That committee was one of the ablest which ever investigated the matter. The members went into the question thoroughly and made valuable recommendations, many of which were adopted. But the most vital recommendation, that engineer officers should in the future belong to the military branch and not to the civil branch, but not to succeed to command, was shelved, and in the failure to adopt that salutary reform is to be found the cause of most of the agitation and dissatisfaction which disturbed the domestic peace of the Navy for more than a quarter of a century, and have again been revived by the recent order.

One of the outcomes of the Cooper Key Committee was the opening of, first, H.M.S. *Marlborough*, and then of Keyham College, as training schools for engineers. Though the latter was starved financially, it had a fine record of success as a technical college, and nearly all the engineer officers who held responsible positions at the Admiralty, in the dockyards, and in the Fleet during the War were men who had passed through its portals.

As it was in the 'sixties and 'seventies, so it was in the 'eighties and the 'nineties. Ships' machinery grew more and more complex, the engineer officers' duties were increased by the addition of new types of machinery, but for all that the Admiralty refused to recognise the engineer as a combatant, and, however absurd it may seem, the officers concerned with the upkeep and running of such vessels as the *Terrible* and *Powerful* were of civilian status.

Through this and other causes the competition for entry into Keyham College, which should have been keen, became almost negligible, and the avenues of entry into the engineering branch had to be thrown open wider and wider while the standard of attainments of the candidates became lower. In spite of this, the numbers forthcoming were insufficient and the staffing of the engine-rooms at the end of last century became so difficult as to constitute a national danger.

This was the position when, through the initiative of the late Mr. D. B. Morison, the engineering institutions of the north took up the question of reform and focussed public attention upon it. Papers were read at Newcastle, Glasgow, and elsewhere, and in 1901 a deputation representing the shipbuilding and engineering world was received by the Admiralty.

The result of this propaganda, together with the difficulties of the authorities in obtaining engineers, was somewhat unexpected. At the end of the year 1902 the Navy was startled with the oft-quoted Selborne Memorandum. Issued by the First Lord, this was really the work of the late Lord Fisher. By that memorandum, the entry, training, and careers of naval officers were reformed from top to bottom. Deck officers, engine-room officers, and marine officers were to be entered together, trained together, serve together, and their duties were to be interchangeable. In the words of the memorandum, every naval officer was to be "a seaman, a gunner, a soldier, an engineer, and a man of science." That scheme, it may be remarked, never had any considerable body of engineering opinion behind it, and many engineers declared it to be impracticable, as experience has indeed shown it to be.

While, however, the Selborne plan of naval training has had to be modified almost out of recognition, it had two excellent features, common entry and equality of status, and these were its chief legacies. The commanders (E.), the lieutenants (E.) who have passed through Dartmouth, were all, until November last, executive officers like lieutenants (G.), (T.), and (N.) who have specialised in gunnery, torpedo, and navigation. They had the same commission, they wore the same uniform, but by becoming engineers had forfeited the right to command. They in fact represented the engineer as suggested by Admiral Cooper Key in 1876 as belonging to the military branch, not the civil branch, but they were not to be allowed to succeed to command.

It may be asked, What became of the older engineer officers who were already in the Navy when the Selborne scheme was introduced? What difference did the new plans make to them? Practically none It is true they were given semi-military titles such as engineer commander and engineer lieutenant, but they remained members of a civilian branch. Th engineer officers who fought in the Bight of Heligoland, who lost their lives at Coronel, and those who drove the *Inflexible* and *Invincible* into action at the Falklands, all fought as civilian officers.

The removal of this anomaly was the result of war. At the end of 1914 the Admiralty made all engineer officers part of the military branch, and thus for the first time recognised their importance. Many were the tributes paid to the engineering branch during the War, and when military status was conferred, Lord Fisher telegraphed to Mr. Morison: "The unapproached efficiency of our engineers in the Navy merited this tardy recognition of their all-important part in the present splendid fighting condition of our whole fleet, and this has been combined with an unswerving loyalty to a changing system which they one and all recognised to be for the public benefit and the good of the Navy." The effect of the new order was felt right throughout the service. The engineer officers were proud of the distinction conferred upon them, and it has been their aim ever since to uphold the highest traditions of the branch to which they were admitted.

It will be seen that the position attained by the naval engineer has only been gained through a long process of evolution. But to-day he unfortunately stands shorn of the military status so tardily given. The Fleet Order of November, by a stroke of the pen, abolishes the military branch and creates a new executive branch from which all engineer officers are excluded. Is it any wonder that parents of young officers, officers themselves throughout the Fleet, and the engineering profession generally, regard the action of the Admiralty as a grave breach of faith? To criticism, the reply is made that the executive officers might equally complain that with the abolition of the military branch they have been deprived of military status. Such a reply is altogether untenable. In a fighting service there must always be a military branch. You may call it by another name but you cannot get rid of it, and to-day the new executive branch stands in the place of the old military branch while the engineer officers are practically reduced to civilian status again.

After all these years, it is indeed high time that the entry, the training, the status, and the appointment of engineers should be placed upon a sound and permanent basis, and Mr. Bridgeman can do the Navy no higher service than by removing these things from the realm of uncertainty, and thus preventing the recurrence of the deplorable controversies which have marked the progress of the naval engineer in the past. The first step, however, is the restoration of military status.

Steel and the Nation.

Metallurgy and its Influence on Modern Progress: with a Survey of Education and Research. By Sir Robert A. Hadfield. Pp. xvi + 388 + 71 plates. (London: Chapman and Hall, Ltd., 1925.) 25*s*. net.

THE author of this handsome volume has played an active part in the metallurgical world, as the head of a famous firm of manufacturers, as an inventor and investigator, and as the president of several technical societies. He has received many public honours, and has been prominent in the life of his city and of the industrial community. Above all, he is personally acquainted with most of the leaders of industry, of physical science, and of education in this and several other countries, and has kept in close touch with related movements, so that he brings to the task of writing a book on metallurgy an exceptionally wide range of experience. From time to time, in presidential and other public addresses, he has reviewed the progress of science and invention, the scope and objects of education, and similar subjects, and it is the material of those addresses, expanded and supplemented by other matter, which has been recast into the form of the present volume, which is well and lavishly illustrated.

The work is not easily classified, being in part a history of metallurgical and engineering industries and of the sciences on which they are based, in part a detailed account of the nature and properties of certain selected systems of alloys, and in part a review of the place of science in the community and of the forms of education best suited to a nation which depends on manufactures for its existence. The metallurgy considered is that of steel, the non-ferrous metals being ignored. The author has written of those things in which he is himself interested, and has made no attempt to construct a systematic treatise.

After a preliminary sketch of the history of the subject, the influence of carbon on iron is considered, leading up to an account of the development of alloy steels. Next follows a description of the two alloys with which the name of Hadfield is chiefly connected, the remarkable manganese steel which was the first of the alloy steels to be investigated thoroughly and still remains unique in its curious combination of toughness and resistance to wear, and the silicon iron which is now in general use for electrical transformers, having a high permeability with a high resistance. The history of these two inventions and of their gradual adoption by the industries is told at length in an interesting fashion, with many personal reminiscences of the men who were associated with the work. The story is most instructive in regard to the importance of research for industry. Other steels are dealt with more briefly, this section containing an account of armour-piercing projectiles, treated in a popular manner, with comparisons with other moving masses in regard to the energy content. Some striking facts concerning steel castings are also included.

Another section of the book is devoted to the subject of fuel economy, and contains some more technical matter in the form of curves and calculations intended to assist the metallurgist in the efficient design and use of furnaces. Stress is laid on the importance of correct design, and on the value of scientific investigations into the flow of gases in that connexion, the pioneer work of Groume-Grjimailo being corrected by the calculations of later workers. The name of Wheeler has been overlooked in this review of fuel economy, although his contributions to the subject are among the most important.

The last portion, dealing with the facilities for technical education and research, is perhaps the least satisfactory, being a collection of paragraphs of very unequal importance, and so failing to produce the right effect of perspective. It is largely devoted to an account of the leading technical and professional societies, beginning with the Royal Society, and as such is of considerable interest, being supplemented by biographical notes on the men who have been chiefly responsible for their growth, but there is only a brief mention of the institutions for the training of metallurgical students, giving an inadequate survey of the facts on a matter which might be expected to receive full attention in such a work. In describing institutions specially designed for research in metallurgy, a detailed list of the apparatus included in the equipment of the Japanese Institute at Sendai is given, without mention of the fact that equally if not more important installations are to be found elsewhere, as, for example, in the National Physical Laboratory, the University in the author's own town of Sheffield, and the Bureau of Standards at Washington, whilst other great laboratories, such as the Metallographic Institute of Stockholm and the Kaiser-Wilhelm Institute at Düsseldorf, produce work of probably equal importance. The omission of the last-mentioned reminds one that the author, in his effort to show that the value of German research in chemistry and the allied sciences has been overrated, almost completely ignores Germany, Wedding and Ledebur being practically the only German metallurgists whose work is mentioned.

Whilst it is legitimate and useful to direct attention to the originality and sound character of English and French research, and to the remarkable industry of the Japanese workers, the effect of such a presentation is to produce a wrong impression, and students of metallurgy at the present day for the most part acknowledge gratefully the value of German research. The great advances in the study of high temperatures due to the labours of the staff of the Geophysical Laboratory of Washington also deserve recognition. Should the author have occasion to revise his work, this defect could easily be remedied, as the information is readily accessible. The lists of distinguished investigators which appear in various parts of the book appear to have been drawn up somewhat at haphazard, and some omissions are certainly quite accidental. Thus, on p. 16, the names of Newlands and Lothar Meyer are omitted from the list of workers on the classification of the elements, whilst lower, under radioactivity, the name of Curie appears without any indication that it covers two investigators. On p. 174, the preparation of the early high-speed tool steels is attributed to Maunsell White alone, Taylor not being mentioned, whilst on p. 292 Ramsay alone is referred to in an account of the discovery of argon, Lord Rayleigh being omitted. Such slips are clearly accidental, and might have been remedied during the reading of the proofs.

The author's enthusiasm for his subject, and his conviction of the value of research, are obvious throughout. As an appendix, he includes a verse translation by L. P. Sidney of an eighteenth-century Latin poem, "Ferrum," by a French Jesuit named de la Sante, containing much curious metallurgical information. The poem was translated into French by Floris Osmond, but has not hitherto appeared in English.

All who are interested in the future of industry should read this book, since the history of alloy steels is typical of modern progress in manufacture, and its lessons have a much wider application than might be supposed from its specialised character.

Medicine in the Middle Ages.

(1) *History of Medicine.* (Oxford Medical Publications.) By Prof. Dr. Max Neuburger. Translated by Ernest Playfair. In two vols. Vol. 2. Part I. Pp. viii + 135. (London: Oxford University Press, 1925.) 7*s.* 6*d.* net.

(2) *The Evolution of Anatomy: a Short History of Anatomical and Physiological Discovery to Harvey; being the Substance of the Fitzpatrick Lectures delivered at the Royal College of Physicians of London in the Years 1923 and 1924.* By Dr. Charles Singer. Pp. xii + 210 + 22 plates. (London: Kegan Paul and Co., Ltd., 1925.) 12*s.* 6*d.* net.

(1) WE have had to wait a long time for the second instalment of Prof. Neuburger's "History of Medicine"; but it is well worth waiting

for. Even though it is only a part of the second volume that he gives us now, it covers the most interesting and romantic phase of the history, a period that few writers could have interpreted with such competence and recognised authority.

In particular, Prof. Neuburger's literary skill gives the book its distinctive character. His lucidity and sense of style make his writing a pleasure to read, and Dr. Playfair has happily transferred these qualities into idiomatic English.

> "Western Medicine in the Early Middle Ages is, strictly speaking, hardly a subject for the historian of science who would present a coherent picture of progressive events—at the utmost sidelights can be thrown upon medical conditions and literature, in as far as the very scanty information at our disposal makes this possible. Inadequacy of scientific principles, total stagnation of investigation, practice devoid of any lofty outlook, stereotyped and primitive, these are the characteristics of this era's healing art, an art which in its manifestations is almost reminiscent of the earliest stages of medical evolution. Gloomy as is the impression left upon the mind, the close connection of medicine with civilisation as a whole and its historic destiny, come unmistakably to the fore, and its fate in this mournful period is bound up more intimately than usual with the spirit of the times."

To deal adequately with this difficult problem called for the wide and exact scholarship and industry which Prof. Neuburger has devoted to his task. He has given us a graphic picture of how Europe gradually emerged from its five centuries of lethargy and acquired from Arabic sources a second-hand acquaintance with Greek medicine. The revival of classical learning completed the process of making Europe the heir to the knowledge of antiquity and the learning of the Greeks.

The present instalment of Prof. Neuburger's book deals with the obscure period of the early Middle Ages, the state of medicine in the eleventh and twelfth centuries, the coming of Arabic influence into western science, and the effects of this upon the development of medicine in the thirteenth century and the later Middle Ages, elucidating the circumstances in which the development of modern scientific methods and the reliance upon direct observation and experiment were introduced.

It is difficult to give a summary of this fascinating work. Every one interested in the history of science will have to read the whole volume for himself. The history contains ample references to authorities, and includes an extremely useful historical survey of literature. It is full of interesting side-lights on the history of civilisation, with which only a man of exceptional knowledge and human sympathy could have illuminated the history of medicine. We may perhaps be permitted to give an illustration of these qualities. Describing the emancipation of science from the shackles of scholasticism—a process which can be seen happening in the case of anthropology in our own day—Neuburger gives this graphic picture of Roger Bacon's unhappy experience as a pioneer before the times were ready for his reforms :

> "Since Albertus Magnus remained without a true successor in the domain of natural science, and never broke the bonds of the prevailing mode of thought, but only succeeded in providing the possibility of a reconciliation within certain limits between unbiassed observation of facts and scholasticism, it cannot be a matter of surprise that the premature movement in favour of the emancipation of scientific investigation from dialectic oppression, on an exact foundation upon a basis of observation and experience by the aid of mathematics and experiment, should find no support, but should be met by misunderstanding, even by embittered enmity. It was the English Franciscan, Roger Bacon, who once more initiated this movement, a truth-seeker and pioneer of comprehensive knowledge and intuitive perception, a thinker of unyielding austerity of thought, who paid for his great superiority over his age with a lifetime's martyrdom, but whose name can never be erased from the annals of the intellectual development of mankind so long as the light of scientific freedom shall shine." (P. 58.)
>
> "Unfortunately the fruitful and almost unique influence of this great man, who aimed at a reform of science and education, was only too early interrupted. Envy and unpopularity which followed on the heels of initial admiration and which grew as the result of certain utterances of Bacon's upon the ignorance of eminent scholars and upon the immorality of the monks, suspicion which caused his incomprehensible scientific researches and superior knowledge to be looked upon as devilish arts, culminated eventually in serious charges which, though for a while repelled, finally found credence amongst his superiors, after Bonaventura had succeeded to the generalship of the Franciscan order. Bacon was taken in 1257 from Oxford to the House of the Order in Paris, where he had to submit to various penalties and was placed under strict supervision, whilst from this time onwards he was deprived of freedom to commit to writing his ideas and discoveries. A last ray of hope penetrated to the investigator thus doomed to silence when the newly elected Pope Clement IV., who in earlier days had been friendly inclined to him, in 1266 extended to him in profound secrecy the permission to elaborate his views and plans for reform and to submit them by way of justification." (P. 59.)

(2) In the Fitzpatrick lectures delivered by Dr. Charles Singer to the Royal College of Physicians in 1923 and 1924, the substance of which is now published under the title of "The Evolution of Anatomy," an interesting sketch is given of the history of anatomy from the earliest times. Men of the Upper Palæolithic period showed their knowledge of the heart in the cave pictures of France and Spain, which seem to indicate that already they had formulated theories of the life-giving power of blood. The Egyptians and the Babylonians struggled

in the dark for many ages before the Greeks got rid of the trammels of hieratic obstruction that prevented the free development of knowledge and rational methods. Dr. Singer's story really begins with the Greeks and follows the history throughout the intervening centuries until our own William Harvey introduced a new epoch in scientific medicine and experimental physiology.

Dr. Singer's book is a comprehensive and lucid story well adapted for the use of medical students and of the general reader who wants an easily understood account of the chequered career of medical science.

One of the outstanding features of the book is the interesting collection of reproductions of ancient anatomical figures; in particular, the illustrations from the "Epitome" of Vesalius. For the teacher of anatomy who cannot devote much time to the teaching of history in the course of his normal work, this book will be particularly welcome, as it provides a body of important information to which every medical student should have easy access. It reveals the age-long struggle that was necessary to acquire the knowledge of human structure and the facilities for studying practical anatomy with complete freedom which the student enjoys to-day. Dr. Singer's book should bring these facts home to him, and also impress upon him a feeling of gratitude and respect for the men who by their own sacrifices secured these liberties. G. ELLIOT SMITH.

The Witch Cult.

Witchcraft and the Black Art: a Book dealing with the Psychology and Folklore of the Witches. By J. W. Wickwar. Pp. 320. (London: Herbert Jenkins, Ltd., 1925.) 8*s.* 6*d.*

INTEREST in the occult is perennial and widespread; but the appeal of the witch is especially strong to all those who cherish their little superstitions but do not take them too seriously. Although real belief in the witch is no doubt dying, it is dying slowly. Reports of cases in country courts in which witchcraft is involved in some way or another are of sufficient frequency to show that it still has a strong hold on the countryside. Quarrels over bewitched cattle, sometimes followed by assaults in which the witch was "scored above the breath," that is, scratched on the forehead, as a protective measure, point to an identity of mental attitude in the modern peasant and his ancestors as far back as we can go in the records of popular and primitive belief.

Mr. Wickwar's "Witchcraft and Black Magic" is a popular account of witchcraft, in the main historical, but written throughout from the point of view of the student of the lore of the folk and the underlying survivals of primitive religion and magic. "Witchcraft," he says, "had its real inception in a period of fear, wonder and sacrifice common to all primitives." He deals with the belief as it existed in England only, excepting for one chapter in which he briefly recounts the rise and progress of witchcraft prosecutions on the Continent, which resulted in an appalling death roll in France, Germany, and northern Italy. Mr. Wickwar traces the history of the cult from the third to the eighteenth century, when the mania of the sixteenth and seventeenth centuries had died down and the attitude of the more enlightened members of the community had become such as is indicated by the change in the law relating to witchcraft brought about by the Act of George II. in 1735. By this Act the real existence of witchcraft ceased to be recognised, and it was relegated to the realm of superstition and fraud. Prosecutions for witchcraft were abrogated, and *pretence* to practise witchcraft became the indictable offence.

The history of the witchcraft belief is extremely interesting, but its exact interpretation is by no means clear. Miss Murray has suggested that witchcraft was a genuine cult, a survival of a primitive ritual practised by the covens—the assembly of twelve witches with their leader—and connected with fertility rites. Pagan rites certainly survived after the introduction of Christianity, as was recognised by St. Augustine according to the records of the Venerable Bede, and documents of the seventh, eighth and following centuries refer to survivals of pagan ritual which might well be the basis of a witchcraft cult. Walter Mapes also describes a ceremonial attributed to an heretical sect in which the procedure is similar in certain elements to a witches' sabbath. In most of the early cases of witchcraft, however, the delinquents are guilty of magical-practices rather than witchcraft in the strict ritual sense. Such, for example, was the attempt by Lady Cobham against the life of Henry VI., and of the Duchess of Bedford, who wished Edward IV. to marry her daughter.

When witchcraft became a form of heresy under the Bull of Innocent VIII., in 1484, the head and front of the offending was not merely the employment of magical means to accomplish some end, but the renunciation of the Church, the voluntary execution of a covenant with the devil, and the entry into the communion of witches. Mr. Wickwar accounts for the difference by holding that in the course of its history between the third and the seventeenth centuries the character of the belief changed. He accepts the view that witchcraft was a really existing cult which had survived from a primitive form, though at a later stage he appears at times to write not quite consistently when dealing with the part played by the Church in conducting the great prosecutions of the fifteenth, sixteenth, and seventeenth centuries. Granting the survival of a great deal of primitive belief in medieval and modern times, a careful examination of the character of the evidence in the great witch trials makes it difficult to accept the survival of a real cult, notwithstanding the undoubted fact that *belief* in its existence had persisted. How real was the latter is shown by the literature extending from the "Malleus Maleficarum" of 1489 to the writings of Webster, Glanville, and Hutchinson, when in the course of the controversy, belief in witchcraft was both a heresy and a test of orthodoxy. This is one of the most interesting and instructive chapters in the history of religion and literature.

Mr. Wickwar's history of the witch touches upon all its more important features, including lycanthropy, the familiar, the flight of witches, and their sabbaths. He describes the most striking of the cases which came to trial in a way which carries the reader with him, while he successfully skirts the more repellent features of the subject. There are a few slips here and there, probably due to misprints; otherwise Mr. Wickwar's work is commendably accurate.

The Theory of Measurement.

The Theory of Measurements. By Dr. Lucius Tuttle and Prof. John Satterly. Pp. xii + 333. (London: Longmans, Green and Co., 1925.) 12*s.* 6*d.* net.

THIS is a text-book for university students taking the ordinary course; its scope is indicated by the following abbreviated list of chapter headings: Weights and measures, significant figures, logarithms, the slide rule, graphic representation, interpolation, measurements and errors, least squares. In their preface the authors defend and, in our opinion, justify the novel practice of separating the study of the principles of measurement from that of its applications. They are pioneers, and as such deserve our gratitude; but gratitude must not prevent a careful scrutiny.

Our chief criticism is that the title is misleading and indicates a serious fallacy which pervades the book. The authors have no theory of measurements. They show no signs of having considered what is common to ll measurement and what peculiar to special forms of t, in what conditions measurement is possible, or what accuracy means. Doubtless a thorough inquiry into these matters would be unsuitable for elementary students; but it has been justly said that the writer of text-book should know more about what he omits than about what he includes; we are certain that if the authors had thought more deeply on these fundamental questions, they would have selected and arranged their material very differently.

In particular, they would not have devoted so large a proportion of their space to errors and adjustments or conveyed throughout the impression that these are the things that really matter in measurement. They are of primary importance in observational sciences, which cannot select their material, or in sciences which can hope to attain only statistical laws. In the experimental sciences, which most concern university students, these things are altogether subsidiary. In them the criterion of good measurement is not whether it provides material suitable for the computer, but whether it makes his work unnecessary. It is far more important to the physicist to be able to get a sharp galvanometer spot and know why all electrical magnitudes should be referred to resistance than to be able to handle least squares and know the relative advantages of various expressions of deviation. Rayleigh, a master of measurement and quite capable of handling the most abstruse analytical methods if he had found them valuable, never, we believe, used any method of adjustment more complicated than the taking of an arithmetic mean. Yet our authors have the hardihood—we had almost said impudence—to offer their students a set of Rayleigh's measurements and suggest that they "reject" some of them by Chauvenet's criterion. In this chapter their full error stands revealed. No wise and honest experimenter "rejects" an observation. He may reject the record of an observation on the ground of clerical error; but a really discrepant observation is more valuable than any other. It is always an indication of the limits of the method; it is often the clue to unexpected avenues of research.

However, we recognise that our authors are merely following an evil tradition, and that their fault here is only that they have failed to advance on their predecessors. But even if their general outlook is accepted, their selection and, still more their order, is open to criticism. On what grounds, other than historical, should all statistics be regarded as "applications to biology"? If angles are measured in Chap. iii., why should areas be relegated to the last chapter? If numerical methods of adjustment are discussed at all, surely some method of smoothing other than free-hand drawing might be described. If over-estimate of accuracy is a danger, surely under-estimate is equally serious; the slide-rule may be "sufficient for the great majority of practical calculations," but it is certainly not for many simple laboratory experiments; there is no instrument the student is more liable to abuse. Much more should be said about computation. Few students can add; and the most important fact about "physical arithmetic" to be instilled into them is that it must be right. Accuracy can be acquired by practice alone, but the lack of it so often leads to a preference of graphic methods over simple numerical methods, both quicker and more satisfactory, that no space devoted to aids and checks would be wasted. Calculating machines other than the straight slide-rule are not mentioned, and tables are regarded as books to be read rather than as instruments to be handled. Lastly nomograms, theoretically interesting and practically most useful, are dismissed in a short paragraph.

We hope then that the authors will try again. They have aimed at writing a book that has long been needed, and their attempt is the best, because it is (so far as we know) the only one in the language. If they can make their execution equal to their design, if they will really justify their title, they will indeed deserve the thanks of all who desire reform in the teaching of physical science. NORMAN R. CAMPBELL.

Our Bookshelf.

Technical Education: its Development and Aims. By C. T. Millis. Pp. vii + 183. (London: Edward Arnold and Co., 1925.) 6*s.* net.

ONE of the chief lessons we may learn from a study of the past is that society is neither "in rigid repose with certain . . . institutions rooted like oak-trees in the centre round which all group themselves as best they can," nor is it in such a fluid state that its institutions may ruthlessly be torn down. Roots there are, but they are not eternal, and, although they are not to be pulled up hastily or thoughtlessly, there are among them those which are removable when they no longer fit life's changing conditions.

Mr. Millis's book—and particularly that part of it which reminds us of the debt we owe to the pioneers of technical education—makes us realise this very clearly, and directs our attention to some of the causes which are gradually forcing all concerned with education to examine their theories and practices so that education shall not be divorced from life. Slowly we begin to understand that careers in industry and commerce are worthy of as careful preparation as are those in the "professions." In secondary schools the need of "modern" sides is being felt: enlightened employers, recognising the decay of the apprenticeship system, are seeing that the means of producing an intelligent and adaptable workman already exist within our system of technical education, and would therefore improve and extend that system.

That there is a national urge to examine these questions may be seen from the fact that they are already receiving attention by the Balfour Committee, the Board of Education's Consultative Committee, and the recent Committee set up by the Boards of Education and Trade. An unofficial committee under the chairmanship of the Right Hon. Lord Emmott is also examining the relationships between technical education and other forms of education and industry. In view of these signs of the times, whether one agrees with Mr. Millis's conclusions concerning technical education or not, his book is a distinct contribution to the discussion of questions which are bound to be much to the fore in the coming reconstruction of our ideas both educational and industrial.

Grundfragen der vergleichenden Tektonik. Von Prof. Dr. H. Stille. Pp. vii + 443. (Berlin: Gebrüder Borntraeger, 1924.) 22·50 gold marks.

THE most valuable part of this important work is the very full account, occupying some 200 pages, of all the epochs of mountain-building since the close of the pre-Cambrian. A very clear picture of the geological structure of Europe is brought out, starting with the primeval Europe of the pre-Cambrian shields, and continuing through the main tectonic subdivisions built up by the successive phases of Caledonian, Hercynian, and Alpine movements. Altogether about twenty definite phases are recognised. Three of these are grouped as Caledonian (Ordovician to Lower Devonian); five as Variscan or Hercynian (Upper Devonian to Permo-Triassic), and the rest as Alpine (Kimeridgian to recent). The broad periodicity often referred to in text-books clearly cannot be accepted except for limited areas. Dr. Stille continues to hold the view that earth-movements are mainly due to the contraction of the outer crust, a theory that is at present subject to very severe criticism from various sources. But although the author says nothing of the possibility of expansion, and little about isostasy, he maintains, in opposition to Suess, that upward movements have occurred not only relatively to downward movements, but also with reference to the centre of the earth. It is a great pity that the details of igneous activity have not been included with those of earth-movements. The task of compiling all the information must have been a heavy one, but a little more work would have sufficed to make the book a storehouse of petrological data of the utmost value. As it is, we are indebted to Dr. Stille for the most complete account that has yet appeared of the earth-movements of Palæozoic and later times.

Electric Vehicles. By Charles W. Marshall. Pp. xi + 96 + 25 plates. (London: Chapman and Hall, Ltd. 1925.) 9*s.* 6*d.* net.

THE class of electric vehicle which has proved mos successful in Britain up to the present time is th lorry of from 1 ton to 5 tons capacity. The autho has had extensive experience of the working of electri battery vehicles belonging to the Glasgow Corporation and he quotes test figures which are very interestin and instructive. He compares the cost for electric petrol, and steam motors and shows that the electri vehicle is cheapest to run, provided that the loa capacity lie between 2 and 5 tons. For loads of les than 2 tons, the petrol vehicle is the most economica But electric vehicles are preferable in every way t horse-drawn vehicles. The average consumption energy for a ten-mile run is generally about a uni It is rightly pointed out that electric vehicle builde are greatly handicapped in their endeavours to indu private firms to use electric vehicles by the fact th most electricity authorities have no vehicles of th type themselves. It would pay the municipal electr authorities if all the city work at present being do by horses were done by electric vehicles. For ea horse displaced a night load on their station of abo one kilowatt for seven hours would be obtaine Valuable data are given which should enable enginee to come to a decision.

Letters to the Editor.

Radiation arising from the Mutual Annihilation of Protons and Electrons.

THE recent work of Millikan (*Science*, 62, 444, 1925) has added to our list of radiations, some of far shorter wave-length than any hitherto discovered. By extrapolation of A. H. Compton's formula for absorption (*Phys. Rev.*, 21, 483, 1923), it has been estimated that these new rays have a range of wave-lengths between 0·0004 and 0·00067 Ångström. (Had the analogous formula developed by Jauncey (*Phys. Rev.*, 22, 233, 1923) been used, the values would have been between 0·0022 and 0·0029) It is suggested in Millikan's article that "the computed frequencies of these rays also correspond closely to the energy involved in the simple capture of an electron by a positive nucleus."

It seems worth while looking into the possible ways in which the capture of an electron by a proton can be effected, and considering how it can be done with the minimum sacrifice of what are usually considered to be basic principles. In attempting to speculate on the origin of extremely high frequency radiation according to the line of thought indicated, it may be well to set down what principles we should endeavour to retain. These are:

(*a*) Conservation of energy.
(*b*) Conservation of momentum.
(*c*) Conservation of charge.
(*d*) Reversibility of process considered.
(*e*) Velocities never to exceed the velocity of light.

(*a*), (*b*), (*c*), and (*e*) need no comment. As to (*d*), a word of explanation may be necessary. From considerations involved in the discussion of Klein and Rosseland's "collisions of the second kind" and implied in Einstein's derivation of Planck's formula, and particularly from the work of R. H. Fowler and E. A. Milne on the equilibrium of ions, atoms, excited atoms, and radiation, it has appeared necessary to demand that each elementary process involving the emission or absorption of radiation and a change of state of the atom, etc., must be individually reversible. It seems desirable in the speculations now under consideration to favour the solution in which the reversibility is not too difficult to realise.

We shall now consider various ways in which a quantum can be produced by the mutual annihilation of an electron and a proton on collision in which the energy of the quantum is supplied by the mass energy annihilated.

The conservation of energy requires that the energy, $h\nu$, in the quantum of radiation generated, should be equal to the combined energy of the proton and electron, Mc^2+mc^2, where M and m are their respective masses.

$$h\nu = Mc^2 + mc^2.$$

If we make no attempt to see that any of the other principles enumerated above are satisfied, we can at once proceed to calculate the wave-length. Neglecting m in comparison with M, we have

$$\lambda = \frac{h}{Mc} = 1\cdot3 \times 10^{-13}\ \text{cm.} = 1\cdot3 \times 10^{-5}\ \text{Å.U.}$$

This is apparently what Jeans has done (NATURE, December 12, 1925, p. 861), for this value is identical with his. It will be observed that this value is thirty times less than the minimum wave-length of the new high frequency radiation as estimated by Millikan.

In the foregoing, conservation of momentum is ignored completely. If we attempt to secure conservation of momentum, then the momentum of the quantum must be equal to that of the disappearing electron and proton. Let us assume that, after collision, the quantum is moving along the OX axis, and that, before collision (which occurs at the origin), the proton and electron are moving respectively with velocities v_1 $(=\beta_1 c)$ and v_2 $(=\beta_2 c)$ and in paths making angles of ϕ and θ with the OX axis. If M and m be their masses, the conservation of energy requires

$$\frac{Mc^2}{\sqrt{1-\beta_1^2}} + \frac{mc^2}{\sqrt{1-\beta_2^2}} = h\nu. \qquad (1)$$

The conservation of momentum requires

$$\frac{M\beta_1 c}{\sqrt{1-\beta_1^2}}\cos\phi + \frac{m\beta_2 c}{\sqrt{1-\beta_2^2}}\cos\theta = \frac{h\nu}{c}, \qquad (2)$$

and

$$\frac{M\beta_1 c}{\sqrt{1-\beta_1^2}}\sin\phi = \frac{m\beta_2 c}{\sqrt{1-\beta_2^2}}\sin\theta. \qquad (3)$$

On multiplying (2) by c, and comparing with (1), it is quite evident that both equations cannot be satisfied simultaneously, since $\cos\theta$ and $\cos\phi$ cannot exceed unity and β_1 and β_2 are necessarily less than unity. There is also a great difficulty in imagining the reverse process, which would evidently require a single quantum to disappear spontaneously, without apparent cause, and a proton and electron to appear in its place. The disappearance of the quantum on collision with some object is conceivable, but its sudden disappearance at some instant, without anything to mark that instant as different from any other instant, is contrary to our notions of cause and effect.

If we consider a three-body collision, between *two* electrons and *one* proton, resulting in a quantum and one electron, we can find a solution which satisfies all the conditions (*a*) . . . (*e*). Let us suppose (as a special case) the two electrons and the proton to be initially at rest before collision and the surviving electron to go off with a velocity v $(=\beta c)$ after collision. The energy and momentum equations are

$$mc^2 + mc^2 + Mc^2 = h\nu + \frac{mc^2}{\sqrt{1-\beta^2}},$$

$$0 = \frac{h\nu}{c} + \frac{m\beta c}{\sqrt{1-\beta^2}}.$$

Solving, we find

$$h\nu = \tfrac{1}{2}Mc^2\frac{\left(1 + 4\dfrac{m}{M} + 3\dfrac{m^2}{M^2}\right)}{\left(1 + 2\dfrac{m}{M}\right)},$$

or, neglecting quantities of the order of m/M,

$$h\nu = \tfrac{1}{2}Mc^2,$$

whence

$$\lambda = 2\cdot6 \times 10^{-13}\ \text{cm.} = 2\cdot6 \times 10^{-5}\ \text{Å.U.},$$

and

$$\beta = 0\cdot999998.$$

Reversibility of the process in this case is easily visualised, for the quantum would disappear only on collision with an electron of energy $(1/2)Mc^2$ (neglecting quantities of the order of m/M). It is evident that the generation of high frequency radiation can result from a three-body collision without violating any of the principles enumerated above. (The quantum and recoil electron will, of course, travel in opposite directions, but there is nothing to determine the orientation of the line in space.)

We can generalise this three-body encounter by supposing that, before collision, one electron is moving with *any* velocity in *any* specified direction, with respect to the direction of motion of the resulting quantum. It turns out that in this case the quantum can have any energy between (1/2) Mc^2 as a lower limit and infinity as an upper limit. A three-body collision between *two* protons and *one* electron resulting in a quantum and one proton will also satisfy all the specified principles $(a) \ldots (e)$. In this case, the energy and momentum equations are

$$Mc^2 + Mc^2 + mc^2 = h\nu + \frac{Mc^2}{\sqrt{1-\beta^2}},$$

$$0 = \frac{h\nu}{c} + \frac{M\beta c}{\sqrt{1-\beta^2}}.$$

Solving, we get

$$h\nu = \tfrac{1}{2}Mc^2 \text{ (approx.)},$$

from which

$$\lambda = 1\cdot7 \times 10^{-13} \text{ cm.} = 1\cdot7 \times 10^{-5} \text{ Å.U.}$$

and $$\beta = 0\cdot6.$$

It is very evident, therefore, that a three-body type of collision is much more satisfactory than a two-body type—as a possible explanation of the origin of the high frequency radiation.

It has been suggested that formation of the helium nucleus from four protons and two electrons will give rise to a high frequency quantum. The value of λ can be shown to be 0·0018 Å.U. It may also be shown that this process will satisfy the conservation of momentum and, moreover, that the reverse process is easily realised, being merely the break-up of a helium nucleus on the impact of the quantum.

It is evident that if we consider the possibility of collisions involving nuclei of atoms other than hydrogen, there is a wider field for further investigation and speculation.

Three Fundamental Frequencies.

IT is possible to equate the quantum and the relativity expressions for energy, and thus to obtain three interesting and fundamental frequencies, with their corresponding wave-lengths.

The well-known quantum expression is $h\nu$, where h is Planck's constant and ν the frequency equal to c/λ, where λ is the wave-length.

On the other hand, the relativity form of energy is mc^2, where c is again the velocity of light and m is the mass under consideration.

We have then $h\nu = mc^2$ or $hc/\lambda = mc^2$,

whence
$$\lambda = \frac{h}{mc} = \frac{6\cdot55 \times 10^{-27}}{3 \times 10^{10} m}$$
$$= 2\cdot18 \times 10^{-37}/m.$$

In the first place, put $m = 9\cdot0 \times 10^{-28}$ gm., the mass of an electron, and we have $\lambda = 0\cdot0242$ Å.U., which would be the wave-length due to the complete disappearance of the mass of a slow electron when, if ever, it reappears as radiation.

If, however, m is given the value of the mass of the hydrogen atom ($1\cdot64 \times 10^{-24}$ gm.), we find λ is $1\cdot33 \times 10^{-13}$ cm. This is the wave-length of the cosmic radiation to which Jeans refers (NATURE, December 12, 1925, p. 861), when he contemplates the disappearance of the equal charges and of the unequal masses of the proton and electron, and their reappearance as the most penetrating radiation of which we have at present any conception.

Finally, we can give to m the value derived from the congestion of four hydrogen atoms, each with atomic weight 1·008, into a single helium atom, with 4 as atomic weight. The available mass convertible into radiation is now $4 \times 0\cdot008 \times 1\cdot64 \times 10^{-24}$ gm. or $0\cdot032 \times 1\cdot64 \times 10^{-24}$ gm. This gives the wave-length λ a value of 0·0004 Å.U., or 4×10^{-12} cm. This is the wave-length of the penetrating radiation referred to by Millikan as of cosmic origin in a recent contribution to *Science* (November 20, 1925, p. 445).

To sum up—

$\lambda = \frac{h}{mc}$ leads to three basic wave-lengths,

	Electron.	H atom.	He from H.
$m =$	$\frac{1}{1800}$	1	0·032

$$\lambda = 0\cdot024 \text{ Å.U.},\ 0\cdot000013 \text{ Å.U.},\ 0\cdot0004 \text{ Å.U.},$$

where m is expressed in terms of the mass of a H atom $1\cdot64 \times 10^{-24}$ gm., and Å.U. denotes the Ångström unit or 10^{-8} cm. The reversals of such transformations, when each radiation changes into its corresponding mass, are readily conceived and may indeed occur in Nature under conditions at present unknown, for indeed such changes are not yet within our experience.

New Mutations in *Gammarus chevreuxi*, Sexton.

SINCE the publication of the account of the first mutations in *Gammarus chevreuxi* (*Journ. Mar. Biol. Assoc.*, vol. 11, No. 3, 1917) a number of new mutations have appeared. Most of these, like the first, are connected with the eye, particularly with its colour and shape, but the most striking of all the new departures is a change in the colour of the *body*.

In the normal *G. chevreuxi* the body is pale green in colour with two bright red patches on each of the pleon-segments, and bars of brown pigment on the antennæ. The fully adult female looks much darker than the male, owing partly to a difference in the green colour, bluish in the female, yellowish in the male, and partly to the dark green, almost blackish, tint of the gonads which show through the transparent cuticle. The eggs, which are dark green when first laid, gradually change to yellow as the embryos form, and then to a deep orange colour just before the young are hatched. In the new mutation the animals are a translucent pearly-white, with no tinge of colour in the body. The gonads show as opaque white stripes, and the eggs in the brood pouch during the whole period from deposition to hatching can only be seen by transmitted light.

We have now three distinct new stocks producing mutations, the stocks having originated from three independent black-eyed pairs brought in from the wild. In all three stocks, as in the original mutating stock, red-eyes appeared which were recessive to black-eyes. We had therefore first to ascertain whether we were dealing with different and distinct mutations, or simply with re-appearances of the old form. To do this, we cross-mated the red-eyed recessives of the four stocks in as many ways as possible. Whichever way the mating was made *the offspring were black-eyed*, thus proving beyond doubt that the mutations of the new stocks are distinct from each other and from the mutations of the original stock. The reversionary blacks, as we call this F_1 generation, have been back-crossed to the parent stocks, as well as mated *inter se*, and give in F_2, as would be expected, blacks, and reds of different constitutions.

Two of the new stocks show some specially interesting features. In the first we have two distinct kinds of red-eyes, one the bright red eye, with the usual brilliant scarlet pigment, and the other a very dark red, almost black at birth. The exceptional feature of the latter is that the dark red colour *lightens* as the animal grows older. Sometimes the eye becomes a brilliant red, indistinguishable from the bright red-eye; at other times the periphery of the eye lightens, and the centre remains dark. But however great the change may be in the colour of the eye, the constitution of the animals remains unaffected, for those which have lost all the dark pigment, and those which have retained the most of it, give the same results in the offspring.

In the second stock referred to, in addition to a new red-eye mutation, the white-body mutation described above arose, and connected with it, or linked to it, new eye-colours appeared, namely, the permanent white and the changeling white. The eyes and bodies of both these on hatching are white, the eyes are as large as in the normal animals, perfect in shape and in the reticulation of white pigment between the lenses, possessing also the deep-seated retinal cells but lacking the coloured pigment usually contained in them. The albinos of the original stock also had eyes which were white and lacking in colour, but in their case the absence of colour appears to be due to the degeneration of the eye, and the normal body-colour was unchanged.

It has proved impossible so far to separate the permanent whites from the changeling whites at birth with absolute certainty, though sometimes the changeling-eyes, especially those arising from a mating of white-eye and coloured-eye, have a more creamy tint than those of the permanent whites, a tint approaching primrose colour.

The permanent whites never develop any colour in the body, the gonads or the eggs, but the eyes appear to be of at least three kinds: the pure white, which never shows the slightest tinge of colour; the flushed white, which has a very faint trace of colour, palest pink or purple in two or three ommatidia in the centre of the eye; and purple white, in which a part of the eye, usually the lower portion, is a faint purple-lilac tint.

The changeling whites arose from a mating of white female and red male. They are practically indistinguishable from the permanent whites on hatching, but rapidly develop colour as they grow, both in the body and in the eyes, until in the adults it is impossible to see any difference between the changelings and the normal red-eyed animals; their bodies are green, the gonads and eggs dark green, and the eyes bright red.

We have had more than 25,000 young from this stock, consisting of:

(1) Black-eyes, normal body-colour, which, mated together, give either (*a*) all black, (*b*) black and red, or (*c*) black, red and white young.

(2) Black-eyes, white-body, giving black and white.

(3) Red-eyes, normal body, giving either (*a*) all red, or (*b*) red and white in the proportion of 3 : 1.

(4) Changelings, which give (*a*) red and white in the proportion of 3 : 1 when mated together; (*b*) black, black and red, or black, red and white when mated with the different blacks; and (*c*) all black when mated with recessives from any of the other stocks.

(5) Permanent whites, which give (*a*) all white when mated together; (*b*) black and white when mated with blacks carrying red, or with blacks carrying red and white; and (*c*) all black when mated with recessives from any of the other stocks. When, however, these permanent whites are mated with reds or changelings of their own stock we get the remarkable result that the reciprocal crosses are quite different; thus, any red male of the stock mated with a permanent white female (white gonads) gives all white-eyed young, consisting of whites and changelings, but the reciprocal cross, white male by red female (dark gonads), gives either all red-eyed young if the female is pure red, or reds and whites if the red female carries white (the one mating of this kind gave 25 reds and 42 whites). Similarly white male by changeling female (dark gonads) gives half reds and half whites (the actual figures are 131 reds, 130 whites), whereas the reciprocal cross, changeling male by white female, gives all white-eyed young, consisting of whites and changelings.

We propose to reserve any discussion of the theory of these different matings until the results have been carried further and the numerical details can be published.

Do we—don't we—what do we—know?

I ESCAPE from Wonderland to find myself in a land still stricken, where Nature has to be taken in lumps. The effect is a little shocking, to one who has been preaching the use of The Looking Glass. Reflexion at the end of the year, indeed, always, tells me that I am a miserable sinner but NATURE (December 19), in a review article on electrical precipitation, makes me out to be a reprobate of a truly awful type. According to one J. S. G. Thomas, whose acquaintance I, unfortunate, do not enjoy, I have dared to "question Simpson's theory" of the development of electricity in thunder clouds, proposed in 1909. Could any crime be more heinous than that of which I am declared guilty: that of bringing in hydrone in explanation of the thunder storm? Apart from the fact, that I have dared no explanation, it is a little difficult to leave the said fair one out, with water, water, everywhere. Even in water, the fundament does do something, I presume.

I do unfortunately find myself unable, at present, to bow to the august authority of a stately meteorologist who says that thunder is made by splitting hairs—in the form of rain drops. Following my friend Paul of Tarsus—overrated person though he be and the unfortunate prototype of that threatening pest of our society, the metaphysician and psychologist, who knows nothing of hydrone and talks only in terms of thinks—I do but suggest that it were well to prove (prufen) the thesis and only hold fast that which is good. No doubt, I am unduly obsessed (as Mr. Wells would say) by or at or with notions derived from the toyings of one Faraday, perhaps an out-of-date philosopher, with a hydroelectric machine devised by a northern namesake of mine.

I am well aware, that the doctrine—"theory" we have no right to call it, as it does not cover the facts—is in accord with the spirit of the times. We live in an age of "splits." A double Bass is only to be found in an orchestra here and there. The road to Mandalay no longer offers any attraction: you can't satisfy at the end, so much glass is being sold, with little beer—glass with scarce "a glass" in it. Still, I have yet to learn that Jupiter Pluvius is overcome by modern methods of "Sparsamkeit" and that he makes noise by shivering his timbers.

If thunder were made of split drops, should there not be much more of it? Moreover, the thunderstorm rains "magnums," never "splits" I believe no bar-parlour will accept the "split" explanation. Meteorologists, I shall be told, don't frequent such places. More's the pity: they would gain sense of humour, if not of proportion They would begin lower down. When I challenge Sir Oliver Lodge and my friend Prof. Millikan of Pasadena to tell me what happens when I rub my stylo on my coat sleeve—well, they hesitatingly murmur something about rubbed-off electrons. I am not taking any at present; the more as I read in a report of the Physical Society, that a piece of flannel may be a happy hunting ground for an explorer with a piece of sealing wax: apparently you can pick up + electricity here and − there, as Tom Tiddler did both gold and silver: for why? As Mr. Belloc has it:

> Here you may put with critical felicity
> The following question: What is Electricity?
> Molecular Activity, say some,
> Others, when asked, say nothing and are dumb.

Even thunder showers are only sometimes negative, I've heard say My feeling is, that we may leave Sirius and its dense companion and instead rub our coat sleeves in wonder We may then make ourselves of some use in this poor loose world, where the protons are supposedly encumbered and overclad with electrons. We are allowing the mathematicians to postulate all sorts of might-be's—and doing far too little to solve the really live problems.

NATURE is again across my path, on the same date (December 19), in a letter on a surface catalytic action in photochemical processes. I will not stop to consider if a "catalytic" action be ever otherwise than a "surface" effect—I have done so in my contribution to the Solvay Chemical Conference (NATURE, August 22, p 294) I would merely direct attention to the paragraph:

"It is a well-established fact that pure hydrogen and oxygen can combine when subjected to radiation of short wave-length," etc

Is it *a well-established fact* that pure hydrogen and oxygen can combine, etc? Do hydrogen and oxygen—the things we so call and know—ever *combine*? Do not their molecules interact and then only when coupled with certain loose companions? Was I not at great pains, not long ago, in NATURE, to direct special attention to H. B Baker's immortal work, often repeated, showing that hydrogen and oxygen do not interact? Is so-called research but a game, like dominoes, to be played without reference to other people's games? What is the use of "research work," undertaken at great expense of private time and public money, if subsequent workers pay no attention to results already obtained, recorded and discussed *ad nauseam*? Such statements necessarily reflect upon the competence of workers. That a mercury surface should exercise the influence described is in no way surprising—indeed, it is to be expected from Lavoisier's observation, that mercury is easily oxidised even when merely heated to the boiling point in air. Let us burn our books, if we cannot use them: they do but encumber our shelves, if left unconsulted and unconsidered.

Lastly, I am across the Huxley lecture (NATURE, December 26). Sir Oliver Lodge has a great name and his opinion counts for much with the public, because of his position in science. Surely, we have the right to ask him to dissociate himself from our body before saying in public: "And what of man? If his death is the end of him, the value of his existence may be doubtful. But if, *as I know* (my italics), that is not the end of him, then there may be infinite progress in store." We of the body scientific know, that we can very rarely say: *I know*, least of all when speaking of the great problem that has exercised the mind of man throughout the ages. Better that we hold on to the advice long since given by the poet:

> O man! hold thee on in courage of soul
> Through the stormy shades of thy worldly way—
>
> . . . . .
>
> Who telleth a tale of unspeaking death?
> Who lifteth the veil of what is to come?

HENRY E. ARMSTRONG

P.S.—On Friday evening (Jan. 22) I listened to an exquisitely clear exposition by Sir Wm. Bragg of his latest X-ray work. At the close, he spoke of quartz and demonstrated the development of an electric charge when the crystal is compressed or heated—attributing this to intramolecular displacements of the oxygen and silicon atoms. I have ventured to point out, that quartz is an electrolytic conductor of very high resistance—"so are we," say Stylo and Flannel—owing to the presence of traces of silicate. *Argal*: the effect may be simply one of frictional electricity

The Boskop Skull.

DR. BROOM's strictures in NATURE of December 19, 1925, on my paper on the Boskop skull, seem to call for some comment on my part.

I am charged, and I hold, unjustly, with inconsistency in regard to my suggested affinities of this "Proto-Bushman"; for my first reference to this theme is obviously expressed in general terms only. Merely in anticipation of what is presently to follow, I remark:—"A careful study of all the essential features of the skull of the Boskop man seems to show . . that he was a *derivative* of Cromagnon man (italics mine), and the progenitor of the Bushman."

With this brief forecast I leave the subject, of set purpose, as is shown by the continuation—"But before these relationships . . . can be profitably considered . . ." This anticipatory reference, then, can scarcely be interpreted as contradictory to the passage which follows on the next page:—

"The Proto-Bushman is supposed (in my Phylogenetic Tree) to have arisen out of the Neoanthropic 'flux' which was to give rise to . . . the Grimaldi people (and) the Cromagnards. . . ." Only by "quibbling" can these statements be considered as inconsistent, either with one another, or the "Tree" to which Dr. Broom refers.

In regard to the size of the brain of this skull, Dr. Broom remarks in his paper (published by the American Museum of Natural History), "If . . . we make a cast of the brain in plaster, and restore it into at least approximately its original condition, and then measure its size, *as I have done* (italics mine), I feel quite confident the capacity will be found to be more than 1900 c.c." This is highly probable. But I venture to doubt whether any anthropologist would "restore" the skull as Dr. Broom has done.

If we keep to the facts, to begin with, we shall start with a skull no more than 205 mm. in length and 150 mm. in breadth. There is not the slightest justification for Dr. Broom's measurements. In this I have the support of Dr. Haughton, who first described the skull. Having most carefully studied and measured this calvaria I am positive on this point.

I am also quite satisfied with the formula I used in estimating the cranial capacity; and this formula has the approval of no less an authority than Dr. Duckworth. In no test to which I have subjected it have I obtained a disagreement, as between it and other tests, of more than 30 c.c., which is a long way from the 200 c.c. cited by Dr. Broom.

Dr. Broom notes that I had a great deal to say "on the easy problem of the cranium." But if one may judge by his own efforts he has much underestimated this "easy problem." It is further noteworthy that Dr. Haughton, Prof. Elliot Smith, and Sir Arthur Keith have also attempted this task, and have each arrived at a different result. But this by the way.

Dr. Broom is deeply pained and surprised at my failure to realise the immense importance of the fragment of the lower jaw found with this calvaria. On this *alone*, according to his own statement, he decided that the Boskop man must be assigned the rank of a distinct species. This conclusion is curious. All of us who examined this fragment, while it was at the British Museum, regarded it as of no importance at all!

In Dr. Broom's paper he enters at great length into the problems which this fragment presented to him; and he arrives at some strange results. There is no need to discuss these at length. Suffice it to say that Dr. Haughton's interpretation of this fragment needs no amendment. He regarded its much worn stump of a tooth as answering to m. 2, and the remains of a socket enlarged by an abscess, as the socket of pm. 1. Dr. Broom, however, has convinced himself that this socket lodged the canine. Had he been more careful in his estimation of the distance between this socket and the remains of m. 2, he would have been less impressed by this fragment.

This jaw, however, even as restored by Dr. Broom, affords no warrant whatever for assigning to this skull the rank of a new species. Save that the teeth are unjustifiably spaced, it differs in no wise from that of a modern Bantu jaw. I can show him its counterpart. Properly restored, this jaw will resemble, much more nearly, that of a Bushman.

Cromwell Road, London, S.W.7.

Discharge of Electricity through Gases.

THE value of photographs of the Stark effect in the analysis of discharges through gases was emphasised by Prof. R. Whiddington in a recent review of the subject (NATURE, October 3, 1925, p. 506).

Discharge tubes of the type first used by Lo Surdo have a small diameter near the cathode. Owing to this fact an intense beam of light traverses Crookes' dark space, where high electric fields are developed. These fields are accurately determined from the Stark effect for any Balmer or other suitable spectral line.

Various field distributions in this interesting region have been reported by different investigators. Anderson found the field to be a maximum at the cathode surface and to decrease with distance therefrom in a nearly *linear* manner. Nyquist first observed a rapid *decrease* in the field *very close* to the cathode. Takamine's photographs show a rapid *increase* in the same region.

The last distribution is characteristic of the simplest tube of a few millimetres diameter with cathode fitted closely to the wall. Starting with this, I have repeatedly obtained first Anderson's (see Fig. 1) and then Nyquist's type by successive enlargements of the original tube very near the cathode. These modifications permit a broadening of the ionic stream with corresponding decrease in current density and field strength. Control of distribution is of some practical importance in the establishment of the highest electric fields obtainable with a given source of high potential.

As a correlating fact, it may be mentioned that when the Lo Surdo tubes I have used operated properly, they did not contain striations. Thus there is no conflict between Whiddington's interpretation of his experiments on striated discharges and the sharpness of Stark components. The sheets of positive ions which, in his opinion, fly through the tube at regular intervals, might be expected to have a very disturbing effect on the electric fields near the cathode. I have often observed well-defined striations in Lo Surdo tubes containing hydrogen and helium. The analysis at such times is quite useless from the point of view of the Stark effect. The blurred lines indicate the presence of weak and variable fields.

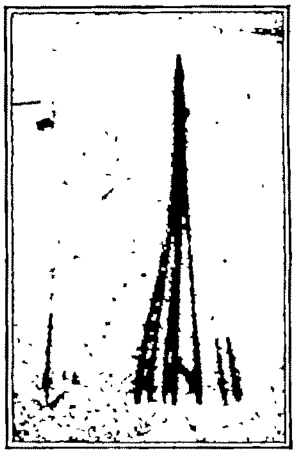

FIG. 1.—Perpendicular components of parhelium line group $\lambda 4144$ in electric fields (single prism spectrograph).

Normal Stark-Lo Surdo photographs, on the other hand, leave one with the impression that the field at a point in the Crookes' dark space can remain constant for hours. A careful examination for a Doppler effect showed that the parhelium atoms which emitted $\lambda 4144$ in Fig. 1 were not moving as a body toward the cathode with any appreciable velocity. These atoms were suspended, therefore, in a field which was probably due largely to neighbouring charges moving with relatively high velocities. Yet the width of each Stark component does not exceed that reasonably expected from the use of a wide slit, from imperfect focussing of the light on the slit, and from a few other disturbing factors.

J. STUART FOSTER.

McGill University,
Montreal, January 4.

The Study of Volcanic Activity on Vesuvius.

ON January 7 I had the good fortune to witness one phase of a minor eruption of Vesuvius in the company of Prof. Malladra, the distinguished director of the Vesuvian Observatory, and I shall be grateful if you will allow me the hospitality of your columns to direct the attention of all our younger geologists and mineralogists to the exceptionally favourable opportunities now presented by the mountain for the study of volcanic phenomena. The great crater left after the violent eruption of 1906 has been gradually filling up, and its floor is now within some 250 feet of the rim. On this floor stands an eruptive conelet, the apex of which is not far below the level of the rim of the 1906 crater, from which its explosions and ejections can be well observed.

The streams of lava which flow from time to time from fissures in the sides of the conelet, and by their successive outpourings are gradually raising the level of the crater floor, can be studied either from the same point of vantage, or else, at quite close quarters, after a scramble to the bottom of the crater by an easy path. On the floor of the crater there can also be studied the chemical changes produced in the lava by the action of hot gases forcing their way up from below, and typical specimens of the products can be readily collected.

These favourable conditions are likely to persist for the next two or three years at least. When, however, the 1906 crater has once been refilled, the activities of the mountain, though likely to become more awe-inspiring and formidable, will be less convenient for study than at present. Further, the presence in London of the admirable Johnston-Lavis Collection of Vesuvian specimens, maps and literature, now conveniently arranged and made accessible for study at University College, affords the English student a unique opportunity of making himself acquainted with the past history of the volcano, either before or after a visit to the locality itself.

In conclusion, it may be not out of place to mention that Messrs. Cook and Son, who work the Vesuvian railway, maintain a comfortable hotel immediately adjacent to the Observatory (Hotel Eremo), at which visitors who stay more than a day or two are received on very favourable "en pension" terms, and from which a large part of the mountain can be conveniently explored. ARTHUR HUTCHINSON.

The Mineralogical Laboratory,
Cambridge, January 25

The Mathematical Tripos.

IN his address to the Mathematical Association, Prof. G. H. Hardy urged the desirability of abolishing the mathematical tripos at Cambridge. May I direct attention to the disastrous results to which such a step might lead in other directions.

New universities are springing up all over England, and they are vying with each other in trying to give as many honours degrees as possible. These are purely examination qualifications, and the professor or lecturer teaching the students has generally no voice in the question as to whether the candidates are to pass or fail. These universities are frequently too poor to be able to keep more than one overworked professor and assistant, who know that unless they can get a good show of "firsts," or even honours people of any class, they will be looked on with disfavour by their colleagues.

No amount of "getting up" questions likely to be "set" or "doing papers" or "working examples and getting the right answer" or "revision" will, however, produce a mathematician, though it may and often does discourage someone that might become one. To my mind the essential requirement for the training of real mathematicians is that they should have followed discourses of lectures given by a large number of real mathematicians, each a specialist in a particular branch of the subject. In my Cambridge days I acquired my mathematical knowledge from about a dozen lecturers, and I am not sure whether the number of qualified lecturers in mathematics (good, bad, and indifferent) runs into two or three figures. I was one myself until I was forced to find employment elsewhere.

Apart from Cambridge there are very few universities possessing a sufficient mathematical staff to qualify any student for an appointment above the standard of an inferior schoolmaster.

If, however, the tripos were abolished, the Cambridge mathematical school would lose the best chance it has of attracting the degree seekers and trying to ram a little decent and intelligent teaching into their over-crammed brains. Personally I should be very sorry if the word "Tripos," which by usage has become the registered trade mark of the University of Cambridge, were abolished. It is in my opinion very unfortunate that they voluntarily surrendered an even more valuable proprietary name in the trade mark "Senior Wrangler" when it was in their power to use this designation as the brand of the best mathematicians of the year, when tested by any method whatever, including research work, even if this test is more or less covered by the Smith's prizes.

Therefore let Cambridge consider seriously before taking any step that will reduce its power of keeping students away from the honours examinations at cheap and nasty new universities. G. H. BRYAN.

Plâs Gwyn, Bangor,
Carnarvonshire.

Domestic Lighting and Heating.

IN the issue of NATURE of December 19, p. 910, an account is given of a house, where heating, cooking, hot water, lighting and power are obtained solely from electric energy. The yearly bill is something like 43*l*. for a ten-roomed house, and, considering that a judicious selection of the several agents available for lighting and heating would perform the same office for less than half the cost, with only very little labour as an offset, but with considerably more comfort, it may be asked where the advantage of the "all-by-electricity" system lies. "There is nothing to do but to operate a tumbler switch." When this has been said, apparently all has been said, for there is nothing tempting in the complicated and costly installation described in Prof. S. Parker Smith's paper, nor in the denial involved by the abolition of the open coal fire (with its appalling waste and its bright cheerfulness!) and of the direct open window ventilation, barred, evidently, by the small supply of heat which can be derived from an electric fire. Unfortunately, these two features, open coal fires and open windows, are essential features of British comfort and British health, and few would shirk the trouble of laying a coal fire with their own hands to spend a long evening by, if the alternative was the simple operation of a switch, and the resulting cheerless glow! I sincerely sympathise with any one who would follow the "simply-a-switch" lure and have but an electric fire to heat in winter a 14 × 22 feet room with a nice spacious window at each end admitting surreptitious draughts in proportion to the amount of light they let in.

The proper solution is not in the direction advocated by Prof. Parker Smith; it is in adjusting one's way of living with the view of a combination of maximum comfort, minimum labour and minimum cost. It is found in the use of a "living room" with an open coal fire (which burns but one scuttleful of coal a day, and, when desired, can be made to last all night, thereby saving the trouble of laying it in the morning). This fire does not require a special domestic servant, nor would its abolition enable one to be dispensed with. A "Sentry" boiler burning small coke (about 2*s*. 6*d*. per week) heats the kitchen and supplies hot water; it burns day and night for five or six weeks on end, requiring only a thorough raking morning and evening. The cooking is done by gas. In the warmer part of the year, hot water is obtained by means of geysers. The other rooms are heated by good gas fires which need but 15 to 20 minutes to bring an icy cold room 17 × 17 feet to a pleasant warmth. The lighting is done by electricity. The result is a comfort which it would not be possible to obtain with an all-electricity scheme. As to the yearly bill, in 1925 it was 18*l.* 11*s.* for a spacious ten-roomed house, this being divided as follows: coal 4*l.* 14*s.*, coke 3*l.* 16*s.* 6*d.*, gas 6*l.* 5*s.* 6*d.*, electricity 3*l.* 15*s.*; well under half the figure quoted by Prof. Parker Smith!

Parthenogenesis in *Methoca ichneumonides* Latr.

IT is well known to collectors of Hymenoptera that the males of the Thynnid, *Methoca ichneumonides* Latr., are extremely rare, whereas the females are sometimes relatively abundant. Neither sex is common and the insect is described by Sharp as "very rare." It has been suggested that the males have been overlooked by collectors, that their life was short, and that their scarcity was only apparent. Recently I have been able to rear these insects in captivity, and my experiments show clearly that parthenogenesis does occur, a fact which readily explains the scarcity of the males.

In July 1924 I caught a number of females of this species near Woking and a single male at Oxshott. These females were provided with Cicindela larvæ, which they stung so as to paralyse them, and on which they afterwards oviposited in the usual way. From the eggs laid by these females a single female emerged in July of the following year. This female was provided with Cicindela larvæ and she was seen to oviposit, although she had never had access to a male In October 1925 I observed that five Methoca cocoons had developed from the ovipositions of this virgin female.

Although I was unable to observe any eggs on the Cicindela larvæ after oviposition by this female, owing to the position of the larvæ in their burrows, there can be no doubt that the cocoons were derived from the eggs laid by this female, and not from eggs aid on the larvæ before their capture. The Cicindela arvæ which I provided for the oviposition were all healthy, lively specimens, taken from open burrows, whereas it is well known that larvæ which have been parasitised by Methoca are very lethargic and incapable of co-ordinated movements of their appendages, he last pair of legs being totally paralysed. After oviposition the Methoca closes the mouth of the burrow of the larvæ, but all the larva I provided were taken only from open burrows.

It will be July 1926 before these cocoons produce magines, when I hope to be able to decide the sex f the inmates. I have opened one cocoon and found he inmate to be still in the larval condition. I hope o carry out further breeding experiments next year nd to obtain sufficient material for cytological work.

So far as I am aware this is the first recorded nstance of parthenogenesis in the solitary Vespoidea.

The Geological Congress and Museums.

THE *Compte rendu* of the Geological Congress held n Belgium in 1922 has just been received at the ritish Museum (Natural History). From it I learn hat there were made in the rules of organisation, reviously formulated in London, certain changes hat call for comment. An attempt, possibly unintentional, seems to have been made to restrict the vitations and the list of those competent to serve n the council to purely professional geologists presenting official surveys. But this was exposed and defeated by the restoration of at least the universities and geological societies to the list. Museums, however, were quite definitely in so many words eliminated from official representation. I beg to raise, and I hope to lead, an energetic protest against this slur on establishments that are a powerful means of promoting geology. Setting aside the Geological and Mineralogical Departments of the British Museum, which in the past have numbered men of rare and world-wide distinction among their officers, I may instance the American Museum of Natural History, the president of which is this year the recipient of the highest honour that the Geological Society of London can bestow, and the geologists and palæontologists of which have of late thrown light not merely on the past history of the Americas but of the Mongolian Desert.

Museums *qua* museums are, let us admit, no more deserving than certain bodies which bear the name of "University" or of "Geological Society." But every geologist will agree that there are many among them doing admirable work for his science. I am astonished that this indignity should have been proposed and supported by my friends E. de Margerie and R. W. Brock, men not wholly unfamiliar with the work of museums.

Perhaps I may explain that the personal question does not enter into this protest, since I can, in another capacity, take a seat on the council.

Circumstances no doubt conspired to render the Brussels Congress less representative of the geologists of the world than it might have been. We may, therefore, hope that this question will be taken up again at the International Geological Congress to be held at Madrid during the last week of May, and that on future occasions an official welcome will again be extended to delegates from the leading museums.

Cirrus at a Lower Level than Alto-cumulus.

ON Sunday, January 24, at about 09·15, the sky was nearly covered with a sheet of alto-cumulus; this had a straight edge, there being quite clear sky low down in the east. In the northern and western parts of the sky and up to the zenith there were numerous streaks of cirrus uncinus, that is, cirrus streaks with the ends upturned; these were without a doubt below the alto-cumulus. All the clouds were moving from about north-west; the apparent motion of the cirrus was faster than that of the alto-cumulus. The upturned ends of the cirrus were to the southward, the streaks trailing away to the northward. The cirrus appeared dark against the clouds above it. The height of the alto-cumulus was measured with a range-finder. Three separate observations were made on different patches of cloud, at angular altitudes of 30°, 22°, and 20°; the heights obtained were 10,500 ft., 10,140 ft., and 10,260 ft. These are in very fair accordance, and there is, therefore, not much doubt that the height of the alto-cumulus sheet was between 10,000 and 10,500 feet; the cirrus must, therefore, have been lower, but how much lower it is impossible to say. The best development of the cirrus was at the time I have named, but some cirrus was seen below the alto-cumulus until about mid-day.

I have long been led to believe that cirrus may occur at a very much lower level than that usually given in text-books on meteorology, but I have never before come across such a very definite case.

The Sennar Dam and the Gezira Irrigation Project.

IN the Sudan, immediately south of Khartum, lies an extensive plain, known as the Gezira Plain, constituting the triangular tract of land enclosed between the two branches of the Nile—the White Nile and the Blue Nile, which unite at Khartum. Some fifteen or twenty years ago this area, comprising considerably more than 3,000,000 acres, was a barren waste. To-day, a substantial part of it is under cultivation and covered with crops.

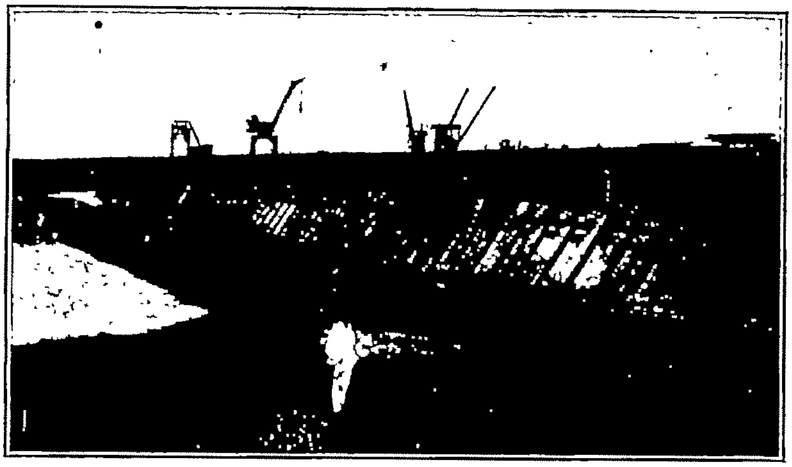

FIG. 1.—Sennar Dam. General view of the works taken from the downstream of the Dam on the west bank on May 1, 1925.

It was Sir William Garstin who, in recent years, first envisaged the idea of rendering this sterile tract cultivable. He put forward the suggestion at the beginning of the present century, and the possibilities of a system of artificial irrigation attracted favourable attention. After due consideration, the project ultimately materialised in accordance with plans prepared by Sir Murdoch Macdonald.

The scheme provided, in the first instance, for the construction of a dam across the Blue Nile at Makwar, a little village a few miles south of the more important town of Sennar. It was not, however, until 1913 that the necessary financial arrangements were completed, enabling the work to be begun in 1914. Suspended more or less during the War, operations were actively resumed thereafter, and the dam, as announced in NATURE of January 30, p. 167, was officially opened by Lord Lloyd on January 21, although the constructional work was actually completed last June, and the irrigation scheme has been in operation since the autumn.

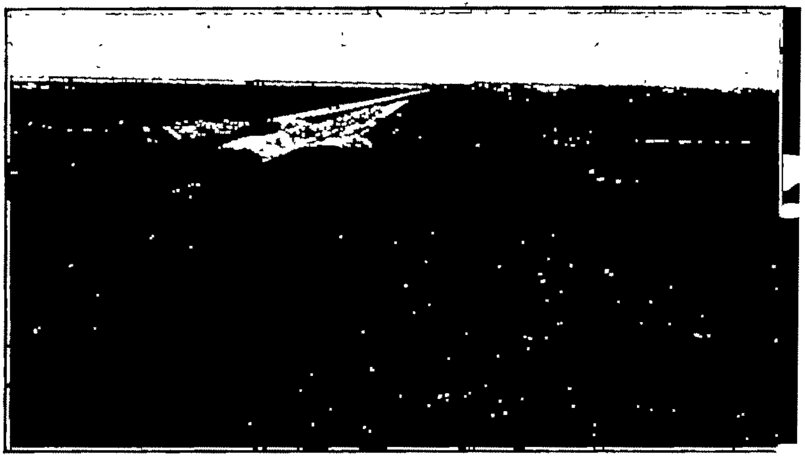

FIG. 2.—Gezira canalisation, March 10, 1925. View of main canal at Kilometre 80 from the Dam, showing a branch canal on the left, and on the right an area already developed and under cotton, and watered by pumps on the river.

Broadly speaking, it may be said that the area which has been canalised and rendered cultivable is equal to the county of Bedfordshire. The total length of main canals is about one thousand miles, and the length of the subsidiary canals is considerably greater. The surface soil is loess (black cotton soil), and the excavation was carried out by drag-line excavators.

The dam itself is an immense structure 3025 metres (nearly two miles) in length, built of granite rubble masonry, which has been founded on an outcrop of gabbro. It is substantially built and contains 422,440 cubic metres of stone and cement. The maximum height of the dam is 39·5 metres and the foundations are carried 10 or 12 metres down below the river bed. The central portion of the dam across the river channel, 1800 metres in length, is pierced by 80 sluices, each 8·4 metres high and 2 metres wide. Above this are 72 small spillways 2 metres high and 3 metres wide, while at each end of the sluice dam there are 20 large spillways, 5 metres wide and 2 metres high. The main canal head regulator, on the western bank, consists of fourteen sluices, 3 metres wide and 5 metres high. The Sudan Government Railway is laid across the dam, and is be extended at a later date so as to connect up wi the existing line at Kassala and so to communica with Port Sudan.

The reservoir formed by the dam is capable containing 636 million cubic metres of water, or, aft allowing for evaporation, 485 million cubic metres. In the cycle of seasonal flow, the reservoir will be filled during November, when the river is free from silt, and the impounding water will be used for irrigation from the middle of January to the middle of April. This reservoir will enable the whole of the natural supply of the upper Nile to be transmitted into Egyptian territory, only that portion of the water being retained in the Sudan for irrigation purposes which would otherwise pass off during flood into the Mediterranean. The present cultivable area lies at a distance of 57 kilometres from the dam and is served by a main canal, 114 kilometres in length. In the process of cultivation, crops will be grown in rotation. Of the 300,000 acres now irrigated, one-third will be assigned to cotton cultivation each year, and 100,000 acres to other crops, of which one-half will be maize, the staple food of the cultivator, and one-half lubia, a leguminous bean suitable for cattle fodder. The remaining 100,000 acres will lie fallow.

The full development of the scheme for the irrigation of the Gezira Plain involves the construction of another dam across the White Nile at Gebel Aulia, about thirty miles south of Khartum. The object of this dam, the construction of which is not yet commenced, is to ensure the summer water supply of Egypt.

The whole project is a remarkable manifestation of the benefits to be derived from the regularisation of forces of Nature, which in their unrestrained condition cause barrenness and waste, but when skilfully controlled add immeasurably to the resources at the disposal of mankind and bring comfort and prosperity in their train.

The consulting engineers for the scheme during the last two years have been Messrs. Coode, Fitzmaurice, Wilson, and Mitchell, who have courteously supplied the photographs reproduced herewith. The contractors were Messrs. S. Pearson and Son, Ltd., represented by Sir Frederick Hopkinson. The chief resident engineer for the Sudan Government was Mr. O. L. Prowde. The cost of the dam structure has been about 5,600,000*l*., or, including the canalisation works, 8,500,000*l*., but with preliminary expenses and other outlays the total cost of the project, so far, to the Sudan Government is in the neighbourhood of 13,000,000*l*.

Smokes as Aerial Colloids.

By Prof. R. WHYTLAW-GRAY.

CONSIDERING the rapid growth of colloid chemistry, it is remarkable that systems of finely divided matter suspended in gases have attracted so little attention from workers in pure science. This is all the more surprising because, on first consideration, such systems appear to be the simplest of all forms of disperse material, and it might be contended that just as the principles of the older chemistry originated from a study of gases, the investigation of aerial suspensions might throw a new light on the many complexities of the colloid state.

Apart from researches in physics which deal with the motions of individual particles mainly of microscopic dimensions, and centre around the question of unit electronic charge, much of the literature in this field is of an applied character, such as, for example, the cause and prevention of dust explosions in coal mines and factories, electrical precipitation, filtration, and settling, and the pathological effects of silicious and other dusts. Information on the stability of smokes, their electrical character and constitution, the size and nature of the aggregates formed on flocculation, is inadequate and meagre, so that the inquirer, unless he is prepared to make experiments himself, is perforce compelled to deduce the properties of these systems from first principles. This is the method followed by Dr. W. E. Gibbs in the very interesting survey of the subject delivered before the Chemical Engineering Group of the Society of Chemical Industry on October 9, and entitled "Aerosols in Industry."

From the literature available, Dr. Gibbs concludes that a close parallelism exists between these systems and the better known hydrosols. Thus smokes in general should owe their stability to the particles all carrying a charge of the same sign, and loss of charge should bring about flocculation or coagulation. The existence of an iso-electric point is assumed, and this it is stated can be reached by adsorption either of gaseous ions or of smoke particles of opposite electric sign. Stability is believed to be enhanced by adsorption from the medium of a protective gas sheath which diminishes the chance of adhesion or coalescence of the smoke particles on collision. It must be confessed that this is an attractive working hypothesis which is supported by the work of Rudge on the charges carried by dusts and also by many observations which have been recorded in the literature.

It seems but a step to go from aerosols to aerogels, and from protection to peptisation, and to assume, as the present writer did some years ago, that the counterpart of all the main characteristics of suspensoid colloids can be discovered in these aerial systems. This, indeed, may prove ultimately to be the case, but in the present state of our knowledge, more is to be gained from a study of the differences than by the pursuit of an analogy which is based on scanty experimental evidence.

Before this view can be tested, it is essential to be able to determine the degree of dispersion in aerosols and to trace how this varies under different experimental conditions. In the case of dusts, many methods are available for estimating the total weight of suspended matter and the number of particles in a given volume, but with the more highly disperse systems consisting mainly of units near the limit of the microscope, to which alone the term aerosol is really applicable, recourse must be had to the ultra-microscope and to special methods of filtration. An attempt along these lines has been made by the present writer and his colleagues. During the last few years a number of fine oxide smokes, composed of non-volatile materials, have been examined in some detail, and it has been shown conclusively that these differ sharply from hydrosols in two fundamental points at least.

(1) These smokes even when dilute are continually undergoing spontaneous aggregation. In contradistinction to the stable metallic sols, they are unstable coagulating systems. No exception to this behaviour has been found, and a non-coagulating aerosol, if capable of existence, has yet to be discovered.

(2) The charged particles in these smokes are never all of the same sign. Usually the oppositely charged units are present in equal numbers so that the smoke as a whole is neutral. Uncharged particles are invariably present and in some cases far outnumber the charged.

The aerosol, then, is not a stable suspension of the primary particles condensed from supersaturated vapour, but is largely a collection of aggregates of a wide range of complexity the proportions of which depend on how far coagulation has proceeded, *i.e.* on the age of the smoke. A corresponding condition in hydrosols is only found during the process of quick coagulation after the addition of an electrolyte.

Whilst the agitation of the particles under molecular bombardment brings them occasionally in close proximity, it is difficult to decide whether electric forces may not play an important part in rendering the collisions effective and so causing aggregation. Analogy may, however, be misleading, and so far no marked difference has been noticed in the rates of coagulation of slightly and highly charged smokes.

A quantitative study of coagulation from the point of view of Smoluchowski's theory is much easier to realise experimentally with aerosols than with hydrosols, for whilst with a gold sol of suitable dilution the process is completed in a few minutes, a dilute smoke alters comparatively slowly and permits the changes to be followed for several hours. It has been found possible, too, with these systems to estimate the size distribution at different periods, for not only does the brightness of the aggregate as seen in the field of the ultra-microscope increase with size, but the rate of fall increases also, so that the desired result can be attained either by a statistical classification of the particles by their brightness or their rates of fall, provided that these can be correlated with the radii with sufficient accuracy.

Now whether the radii calculated by means of the Stokes-Cunningham equation from the observed rates of fall are even approximately correct depends on the structure of the complexes. If these are compact and formed by the true coalescence of the primary units, the calculated radii will not be much in error even if the particles are irregular in shape and not truly spherical. If, however, the complexes or aggregates consist of units not actually in contact but separated from each other by minute interspaces filled with air, the mean density of the aggregate will be much smaller than that of the primary particles from which it is formed, and unless this is taken into account the radii deduced will be found to be much too small.

It is clearly necessary to know, to a first approximation at least, the mean densities of these composite particles. Millikan's oil drop method for determining the value of the unit electronic charge requires a knowledge of the density of the suspended droplet; conversely, the density of a suspended smoke particle, provided that it is roughly spherical in form, can be calculated from its rate of fall under gravity in conjunction with its rates of rise in a known electric field when carrying different charges. If the number of charges on the particles is known and the value of the unit charge is substituted in the equations, the mean density of a smoke complex can be deduced.

Considerations which cannot be discussed here make it probable that the rate of fall of these complexes is represented closely by the Stokes-Cunningham equation, provided the structure is not too loose and that the packing is close. Experiments along these lines have been made recently in my laboratory, and it appears that the composite particles in smokes of magnesium oxide, mercuric chloride, mercury and silver, possess densities varying from one-sixth to one-eleventh of that of the material in bulk, whilst coagulation in paraffin oil smoke gives particles of normal density, *i.e.* true coalescence takes place and homogeneous spheres are formed.

It seems probable, therefore, that any smoke formed by high temperature volatilisation must contain large numbers of these aggregates, and it is not surprising that the use of such particles by Ehrenhaft and others for finding the electronic charge should lead to erroneous values.

From the foregoing, it follows that the true radii of the majority of smoke particles are very much larger than has been supposed, and even in fine smokes usually exceed 3×10^{-5} cm., so that in many cases the supposed ultra-microscopic particles are really of microscopic dimensions. Recently, with a suitable optical system, it has been found possible to resolve these complexes when suspended in the air, and when this is done, the interesting fact emerges that the constituents, though closely joined together, are capable of independent Brownian motion. The smoke particle thus appears to be a system of primary units in dynamic equilibrium under the opposing forces of Brownian agitation and electrical or cohesional attraction.

It is probable that many of the properties of smokes can be explained by this structure of the complex aggregates, such as the low density of electrically precipitated smokes, and the fact that in some cases such material is peptised by weak acids or alkalies to form colloidal solutions as observed by Kohlschutter and Tuscher: the large amount of air carried down by zinc oxide fume and by carbon black pointed out by Gibbs; the immediate resolution of the large flocks of some smokes into their constituent particles on wetting; as well as the apparent stability consequent on their slow rate of diffusion and settling so marked in many fine industrial smokes.

Much work of a fundamental character is needed to elucidate the many aspects of these systems. Next to nothing is known definitely of the conditions under which ions are caught from the air and the particles acquire electric charges. The same may be said about the adsorption of gases by this type of finely divided material and also of its catalytic activity. Again, the investigation of systems composed of liquid droplets or of solid units of appreciable vapour pressure has scarcely been attempted. Indeed, the whole field of aerosols presents many interesting features and its further exploration is likely to yield results of much interest and importance.

Obituary.

Prof. Camillo Golgi.

PROF. CAMILLO GOLGI, member of the Italian Senate for a number of years, Nobel Prizeman in 1906, died on January 21. Though almost eighty-four years of age, he had preserved until a short time ago the astonishing lucidity of his marvellous mind, and when I saw him last in January 1924 he was still taking part in the public life of his country and scientific activities of the University of Pavia, where he had obtained his medical degree in 1865 and had become extraordinary professor of histology in 1875. Towards the end of that year he went as professor of anatomy to the University of Siena to return a few months afterwards to Pavia, where he occupied the chair of general pathology and histology until 1918, the year of his retirement from active teaching.

Son of a distinguished medical practitioner and for some time a pupil of Mantegazza, Bizzozzero and Lombroso, Golgi spent the first years of his career in the Home for Incurables of Abbiategrasso in the Province of Milan, where he went as chief resident physician. Abbiategrasso was in those days a village remote from any centre of scientific activity, and one can easily imagine how inadequate must have been the means of investigation with which young Golgi had to content himself. It was, however, in Abbiategrasso that he wrote his early papers on the history of pellagra, the etiology of mental alienations, the structure and development of Psammomata, the changes of the lymph-vessels of the brain and the structure of the neuroglia, which even now can be consulted with profit. But it was in that Hospital that he discovered his chromate of silver method by means of which nerve cells, with all their processes and the finest ramifications of the latter, can be seen singled out and intensely stained black against a transparent yellowish background. At a time when histological technique was in its infancy, and the structure of the central nervous system looked like an impenetrable mystery, Golgi's discovery revealed the existence of an unforeseen world. A first hint of the new method was given in his paper on the grey substance of the brain (1873). However, the so-called slow process was fully described only in 1875, and the bichromate and mercury chloride method in 1878. The rapid process was first published in his paper on the structure of medullated nerve-fibres (1880). All of them and the mixed process were again minutely described in the last chapter of his monumental work " Sulla fina anatomia degli organi centrali del sistema nervoso," published between 1882 and 1885.

By means of Golgi's methods the microscopic anatomy and physiology of the central nervous system were placed on the sound foundation on which they at present rest. He had since 1873 observed the long- and short-axoned nerve cells with which now every medical and science student is familiar, and the collaterals arising from the axon of the cells of the I type. Already in 1874 he had described the large nerve cells of the granule layer of the cortex cerebelli which bear his name, and pointed out that the "granules" are in fact minute nerve cells. In 1875 he had been able to give a first description of the structure of the olfactory bulb, and to show that both the olfactory fibres and the protoplasmic processes of the mitral cells arborise within the olfactory glomeruli. But it was only in his main work that he set forth definitely the results of his fundamental studies on the morphology and relations of nerve cells, the central origin of nerves, the architecture of some cerebral convolutions, the structure of the cortex cerebelli and hippocampal region, with the addition of fresh observations on the morphology, connexions with blood-vessels and histogenesis of neuroglia cells.

Golgi's description of the diffuse network (*rete nervosa diffusa*) was the anatomical corollary of these investigations and of those on the structure of the spinal cord (1880 and 1890). As he observed in various papers and again in his lecture at Stockholm, his diffuse network consists essentially of the collaterals of the axis-cylinder of the long-axoned cells, the complicated arborisations of the axis-cylinder of the short-axoned cells, and the collaterals and arborisations of the axis-cylinder of the motor and sensory nerve-fibres which reach any given region of the nervous system from others. He always considered the diffuse network, not as a working hypothesis, but as a well-defined anatomical entity linking together the different parts and functions of the nervous system. He was, however, extremely keen on pointing out that it is immaterial whether the thin filaments composing the network actually anastomose with one another or are simply superimposed to form thick interlacements. In other words, the continuity of the innumerable and non-insulated nerve-fibres which permeate the grey substance was in no way necessary to his conception of the united action of whole groups or layers of nerve cells or even entire regions of the central nervous system. For these reasons he persistently refuted the neurone theory, though based on the results of his methods, and could never agree to the individual action of nerve cells postulated by this doctrine.

Mention can only be made of other discoveries, such as the sensory end-organs of tendons (1880), the exact course of uriniferous tubules (1889), and the secretory canaliculi of the oxyntic cells of the gastric glands which Golgi succeeded in impregnating at the same time as Erik Müllar (1893). The pericellular investment and the internal apparatus of nerve cells were described in the same paper in 1898 and the neurofibrils of the superficial portions of nerve cells in 1900. In 1908 he published his arsenious acid method for the demonstration of the internal apparatus, and, by showing (1909) that this cell organ may in glandular epithelia become shifted from its ordinary position, he anticipated the results of recent investigations regarding the important part that the apparatus probably plays in secretion.

Of Golgi's researches in the field of pathology, it will suffice to recall his observations on malaria (1885–1893). After Laveran's discovery, Golgi gave a masterly description of the parasites of the tertian and quartan fever and their non-sexual cycle of development. By showing that the beginning of fever in malaria coincides with the sporulation phase, taking place at intervals definite for each species of the parasite, he led the way to the rational use of quinine in the struggle against this scourge of humanity.

C. Da Fano.

Mr. C. M. Doughty.

We regret to record the death on January 20 of Mr. Charles Montagu Doughty, the famous traveller in Arabia and poet, at Sissinghurst, Kent, at eighty-two years of age. Mr. Doughty was born on August 19, 1843, at Theberton, Suffolk. He was educated at Portsmouth, and later, on failing to enter the Navy, with which he was closely connected through his mother's family, he went to King's College, London, and Caius College, Cambridge. He took his degree, however, from Downing, to which he had migrated from Caius, obtaining second-class honours in natural science (geology) in 1865. During his career as an undergraduate he had shown a taste for antiquarian exploration, which he continued after taking his degree, spending some years in travelling and study. In 1866 he published a short pamphlet on the Jöstedal-Brae glaciers of Norway, where he had spent a year as an undergraduate. In 1870 he went to Holland, where he acquired Dutch and Danish, thence to Italy, Spain, and Greece, crossing over to Palestine a year later.

In 1876 Doughty began his journeys in Arabia upon which his reputation as a traveller and scholar chiefly depends, and for which he had prepared himself by familiar intercourse with the Arabs and expeditions to Egypt, the Sinaitic peninsula, and Petra. He had been attracted by accounts of Nabathæan and Himyaritic monuments at el-Hejr, near Medain Salih. Disguised, but not very successfully, as an Arab, under the name Halil, he set out with a pilgrim caravan from Damascus in 1876, and for nearly two years he was alone among free Arabs, living their life in the desert and in the oases. From the notes made by him the first chart of the superficial geology of the Arabian peninsula was compiled, and he first described the main hydrography of the northern half of the peninsula in communications to *Globus*; but he had become interested in the life of the people, and it is this side of his studies which gives the attraction and value to his great work, "Travels in Arabia Deserta," which was not published until 1888, and then only in a comparatively limited edition.

Partly owing to the fact that his interests were diverted into other channels, recognition of the great value of Doughty's work came late. In 1908 Oxford made him a Doctor of Letters, ***honoris causa***. A little later Caius College elected him an honorary fellow, and in 1920 his University of Cambridge gave him an honorary degree. In 1912 he received the gold medal of the Royal Geographical Society, and in 1922 he was elected an honorary fellow of the British Academy. It was, however, only during the War that his work came fully into its own, his book being made the chief guide and work of reference for our military and political staff operating in Arabia.

We regret to announce the following deaths:

Dr. Walter D. Hunter, chief of the section of insects affecting southern field crops of the Bureau of Entomology of the U.S. Department of Agriculture, who was known for his work on the cotton boll weevil, on October 13, aged forty-nine years.

Mr. B. N. Peach, F.R.S., formerly district geologist on H.M. Geological Survey, on January 29, aged eighty-three years.

News and Views.

An article on "Primitive Law and Order" by Dr. B. Malinowski, which appears as a Supplement to this issue of Nature, raises broad questions of vital interest to anthropological investigation and theory. Taking as his starting-point some of the social and economic activities of the natives of the Trobriand Islands, Dr. Malinowski has asked what is the binding force, the sanction, to use the legal phrase, responsible for their punctual and faithful performance. The conventional answer of current theory he finds by no means satisfactory. The communistic ideas which have been attributed to the Melanesians do not cover the facts. Dr. Malinowski has no difficulty in showing that the "communistic canoe" is, as a matter of fact, not communistic at all. Nor is any greater measure of reality to be attributed to the unquestioned obedience which primitive man is supposed to yield to custom backed by taboo and religious belief. Primitive man is no less unscrupulous than his civilised brother in evading his obligations if he can do so with impunity. Dr. Malinowski has put his finger on an inconsistency between theory and fact which has appealed to some, at least, both in the field and in the study. It has given rise to an uneasy feeling that an observer, not necessarily superficial, may have found by unconscious selection among the multifarious activities of the daily life of a primitive people, very much what he set out to seek. An apparently hasty conclusion has inevitably followed. Dr. Malinowski has attacked the problem by a new method and from a new point of view. He has taken certain concrete cases in primitive economics and social organisation and, by a searching analysis of the facts, shows that the conditions are such that no terms such as 'communism' or 'individualism' can be considered appropriate. The relations of individuals engaged in any economic or social activity depend upon a system of mutual obligations or reciprocities which might be regarded as something analogous to a system of 'civil' as opposed to 'criminal' law. Those who follow Dr. Malinowski's convincing argument can scarcely fail to endorse his plea for the application of his method and point of view to fields other than that in which he has employed them himself.

In 1885 a forest school for the training of the upper subordinate staff of the Indian Forest Service was established at Dehra Dun. In 1906 the Forest Research Institute was inaugurated during Lord Curzon's Viceroyalty. It was placed at Dehra Dun and the old school was given the status of a college, and courses were instituted for training members of the Provincial Forest Service. Research work proceeded slowly at first, since no accommodation was available. Grants were made and a fine Research Institute building was opened in 1913, it being considered at the time that ample accommodation had been provided for research for at least twenty years. The Institute grounds covered 47 acres, the land costing R. 1,68,000, and the buildings, including workshops, R. 5,08,000. The War period witnessed a great development. The forces on the eastern fronts had to depend mainly on India for their requirements in timber, fuel, fodder, and so forth. Great calls were made on the Institute, especially on the economic and utilisation side. By the end of the War, the Government of India recognised that the Institute had already outgrown the accommodation provided in 1913. A large project was accordingly drawn up. An area of 1300 acres was purchased a few miles outside Dehra Dun and plans for a new Institute building, laboratories, workshops, officers' quarters and offices were prepared, the new scheme being estimated to cost R. 1¼ crores.

THE most urgent need at Dehra Dun was for new economic laboratories for timber testing, impregnation, seasoning, paper pulp, etc., and for up-to-date machinery. These latter were all erected and at work before the close of 1924; one wing of the new Institute building was also under construction. To some extent the work was checked under recommendations of the Inchcape Retrenchment Committee, which considered that much of the research work could be left to private enterprise. Under the new Reforms Act, a certain section of Indian opinion wished to have the training of the probationers for the Imperial Forest Service carried out at Dehra Dun, and both the Legislative Assembly and the Council of State passed resolutions to this effect, so far at least as Indians were concerned. Under these proposals, the old Research Institute building was to be adapted for educational purposes. The *Times* of January 23 published a telegram from Delhi stating that the Finance Committee has sanctioned a sum of 833,000*l*. to be spent on the Research Institute. The wording of the telegram is somewhat ambiguous, but it appears to imply that the money has been granted for the development of both research and education in the above-described directions.

THE problem of checking cruelty to animals is one which particularly interests men of science, partly because cruelty is so often due to laxity of thought, and partly because the doctrine of evolution has discredited the view that animals are senseless automata and of importance only in so far as they affect man's welfare. Indeed, the fanatical hostility which Darwinism has encountered is largely attributable to an exaggerated contempt for them, and to consequent resentment at being connected with them by descent: it was, perhaps, not by coincidence that Charles Darwin and Russel Wallace were both earnest champions of the animals' cause. But if animals are far better off in Great Britain to-day than they were a hundred years ago, and than they still are in France, Italy, and most other countries, the improvement must be attributed largely to specific educational work such as that which has been fostered by the Royal Society for the Prevention of Cruelty to Animals. That work needs, however, to be extended, for we still meet with cruelty which arises, sometimes from vice, but more often from apathy and lack of imagination. A key to further extension appears to lie in the hands of university students, many of whom become teachers in after life, and accordingly an attempt is being made to provide machinery (in the University of London in the first instance) for directing the attention of students to the whole problem. To ventilate the proposal, the Students' Union of Birkbeck College is arranging a historical lecture on the subject on Friday, February 12, at 8.15 P.M., and at this, we understand, all readers of NATURE will be welcome. It is hoped that a large number of students and members of college staffs will support the attempt: they should send their names to Capt. C. W. Hume at Birkbeck College, London, E.C.4. We understand that the movement is already assured of the guidance of several experienced veterinary surgeons and biologists.

A WEEK or two ago a case of assault on an alleged witch, which came before a magistrate at Tipton, attracted no little attention; but the trial at Melun, in France, of a case of assault on a priest, is even more remarkable. Abbé Desnoyers of Bombon, the victim of the assault, was set upon and beaten by a party of men and women with the object of driving out the diabolic possession which had enabled him to interfere with the miraculous manifestations of an image of the Virgin, the object of a cult of which a Mme. Marie Mesmin, an illiterate former concierge of Bordeaux, was the head. The accused arrived at the court wearing black veils and spectacles, said to be as a protection against photography, but more probably as a protection against malevolent spells, as it was only with difficulty that they were persuaded to remove them while giving evidence. One of them identified the Abbé with Satan himself, and stated that he had sent diseases to Bordeaux by means of birds, by which he himself (the witness) had been affected, as well as Mme. Mesmin. He also said that the Abbé could inflict death on any one he liked within twenty-four hours, with or without suffering. He possessed dolls in which pins were stuck to injure his victims, and transmitted spells by birds. Mme. Mesmin had cried out between 12 and 2 o'clock in the morning, "The Abbé Desnoyers is killing me; get rid of him." It is interesting to note exactly the same accusations being made in the twentieth century as were made in the witchcraft trials in England and on the Continent in the sixteenth and seventeenth centuries. One of the prisoners said a priest sold to the devil was all-powerful. This was fully in accord with the remarkable frequency with which in France witchcraft has been connected with priests, the case of Grandier in the seventeenth century being, of course, the best-known instance.

"THE Arrival of Man in Scotland" was discussed by Dr. James Ritchie at the meeting of the Edinburgh and Lothians Branch of the Royal Anthropological Institute, held on January 19. Dr. Ritchie stated that the first men of whom evidence has been found reached Scotland at or shortly after the period of the 50-feet beach, when the sea stood at a considerably higher level than it does now, and the Firth of Forth penetrated inland far beyond Stirling. Along its margin in the Carse of Falkirk are many kitchen-middens, and in Oransay and a few other prehistoric settlements on the west coast, clear evidence has been found of the presence of a people of Azilian culture. They appear to have reached Scotland during a period of moist climate, perhaps some 9000 years ago. The Azilian men had no domestic animals and were unfamiliar with even the simplest agriculture. They lived solely by hunting and fishing, a large proportion of their food being made up of the common shell-fish of the sea-shore. They were sparsely scattered, probably never exceeding sixteen to the square mile. Vegetation was very similar to that of modern times except for the extensive forests and broad marshes. But many animals long extinct in Britain roamed in the forests or bred in the marshes or plains. Of the larger forest creatures, elk or moose, reindeer and the extinct wild ox or urus were common. The beasts of prey included the brown bear, the lynx (found only near Inchnadamph), and the wolf. Amongst smaller animals were the extinct northern vole, the lemming, and the beaver. Birds were represented by the great auk on the sea coast, by the forest capercailzie, the bittern, the crane, and the great bustard, all of which have since died out.

THE third annual meeting of British zoologists was held on January 9 in the rooms of the Zoological Society of London. Fifty-seven zoologists were present, and Prof. Graham Kerr occupied the chair. Among the more important contributions were the following: Dr. Bather referred to the importance of writers on zoological subjects following the generally accepted rules of zoological nomenclature and systematic work, and the view of the meeting was clearly that he should write a short paper to make the rules more readily accessible to workers. Prof. Stanley Gardiner spoke on the importance of entomology and moved "that this meeting of British zoologists, recognising the importance of entomology as a growing branch of zoology, both from a scientific and from a practical standpoint, urges greater provision in the British and other Museums and extended teaching and research facilities in the universities." This was carried unanimously, as was also a further resolution, "That this meeting of British zoologists represents to the Prime Minister and the Trustees of the British Museum the urgent need for an extension, both in space and in staff, of the Entomological Department of the British Museum." Prof. Douglas Laurie reported upon the progress towards the establishment of a diploma in zoology and also upon the progress of the library co-operation scheme. A discussion upon "the desirability of linking together the biological sciences," opened by Mr. C. Pantin, raised the question of the advances in modern zoological teaching and brought out views upon the physiological aspect as opposed to the morphological in the training of the student. The next meeting will be held on January 8, 1927.

THE *Times* of February 1 had an article on "The Rainfall of 1925," by Mr. R. Corless, superintendent, British Rainfall Organisation, Meteorological Office. The rainfall, as a whole, was only slightly above the average value, but the distribution of the fall presented some interesting and remarkable features. Over part of Hampshire, including the Isle of Wight, the year was the wettest since 1868 or before, but June was absolutely rainless. Other areas without rain in June included the western part of Cornwall and of Pembrokeshire, a tract at the head of the Bristol Channel, and several smaller areas on the south coast and in the Midland counties. At St. Martin's, Guernsey, it was the first rainless calendar month in an 82 years' record. Over England generally, the drought set in about May 30 and ended on July 1. A map is given showing the rainfall over the whole of the British Isles. The most striking feature of the map is said to be that the area in the south of England extending from Newhaven to Weymouth had an excess of the average for the year amounting in some cases to 40 per cent. At Ventnor the total fall was 41·25 in., and was the highest value since observations began in 1839, except for a total of 42·05 in. measured in 1852. The totals for Brighton and Yapton (near Littlehampton) were the largest ever recorded in 51 and 60 years respectively.

AT the meeting of the Illuminating Engineering Society on January 21, Mr. Eric Farmer, of the Industrial Fatigue Research Board, read a paper dealing with the lighting of coal mines, in the course of which he described experiments illustrating the benefit of screening the filaments of miners' lamps, preferably by a translucent coating on the inside of the protecting glass cylinder. Dr. H. S. Elworthy contributed data showing an apparent benefit, in cases of nystagmus, of a yellow-tinted glass, and for this several explanations were offered. It was suggested that this colour aids the miner in distinguishing bluish shale from black coal, that it is favourable to definition, and that the fact of the periphery of the retina being relatively insensitive to yellow light at low illuminations may help to check movements of the eyeball characteristic of nystagmus. There was a general recognition of the need for higher candle-powers, and a lamp operating with a 4-volt battery and yielding four times as much light as the ordinary lamp, though nearly twice the weight, was exhibited. The need for a standard specification for bulbs used in miners' lamps was pointed out, and it was emphasised that the demand for a life of 1000 hours is excessive for 2-v. lamps, resulting in a poor efficiency and feeble light Prof. Thornton, in a written contribution, suggested the possibility of ordinary methods of electric lighting in mines, based on the use of special cables fed by a low voltage high frequency alternating current, such as had already been found practicable for signalling purposes.

AT the anniversary meeting of the Royal Anthropological Institute held on January 26, the following officers for the ensuing year were elected: *President*, Mr. H. J. E. Peake; *Vice-Presidents*, Mr. C. O. Blagden, Prof. Percy Newberry, and Mr. R. W. Williamson; *Honorary Treasurer*, Dr. F. C. Shrubsall; *Honorary Secretary*, Mr. E. N. Fallaize; *Honorary Editor*, Mr. H. J. Braunholtz.

PROF. G. B. BROWN, Watson Gordon professor of fine arts, University of Edinburgh; Prof. A. S. Eddington, F.R.S., Plumian professor of astronomy, University of Cambridge; and Prof. T. Okey, professor of Italian, University of Cambridge, have been elected members of the Athenæum under the provisions of Rule II. of the Club, which empower the annual election by the committee of a certain number of "persons of distinguished eminence in science, literature, or the arts, or for public services."

IT was announced at the ordinary scientific meeting of the Chemical Society held on January 21 that the Council had received with sincere regret that afternoon the resignation of Dr. Arthur W. Crossley from the office of president, owing to ill-health. Prof. H. Brereton Baker has been nominated by the Council to the office of president. The annual general meeting of the Society will be held this year at Manchester on March 25, the annual general meeting being held in the University at 4 P.M., and the dinner in the Midland Hotel at 6.30 for 7 o'clock.

PROF. J. BARCROFT will deliver a lecture entitled "Hæmoglobin" before the Chemical Society on Thursday, February 11, at 8 P.M., in the Chemical Laboratory at University College, Gower Street, London, W.C.1. The lecture will be followed by demonstrations by Dr. Hartridge and Dr. Roughton, of a method of measurement of rapid velocity constants; by Dr. Keilin, of cytochrome in animal and vegetable tissues; by Prof. Barcroft and Dr. Hecht, of a method of measurement of equilibrium constants; by Mrs. Kerridge, of a glass electrode; by Mr. R. Hill, of porphyrins of the heavy metals; and by Mr. G. S. Adair, of measurements of osmotic pressure of hæmoglobin.

AT a meeting of the British Mycological Society held at University College, London, on January 23, Mr. Chaston Chapman dealt with the advantages to be gained by the foundation of a National Institute of Industrial Micro-biology, and the following resolution (proposed by Mr. F. T. Brooks and seconded by Prof. Dame Helen Gwynne-Vaughan) was put to the meeting and carried unanimously—"That the members of the British Mycological Society at their meeting held at University College, London, on January 23, 1926, are of the opinion that it is most desirable that a National Institute of Micro-biology should be established in this country."

DENMARK now possesses a sanctuary for the native fauna and flora, in an estate transferred to the University of Copenhagen, by the munificence of a private citizen. The property is that called "Strodam," near Hillerod, some 30 miles north of Copenhagen, and south of Elsinore. It comprises about 300 acres, and is to be a perpetual sanctuary for native animal and plant life to be preserved in the interest of natural science. The donor is Mr. Axel Jarl, whose family are well known for their munificence for any object of national benefit. Zoologists and botanists both of Denmark and other countries are indebted and will be grateful to Mr. Jarl for his practical if sentimental tribute to his native land.

ARRANGEMENTS are proceeding for the International Archæological Congress in Syria and Palestine which is to be held under the patronage of the two High Commissioners at Beirut in April next. Invitations have already been sent to a large number of representative bodies to appoint delegates to the Congress, and a revised programme of proceedings has now been issued. The work of the Congress will be arranged in three divisions, first ethnological and prehistoric, second ancient history, and third medieval and modern. Delegates are, however, asked to assemble in Jerusalem on April 2 for a special programme covering the week preceding the opening of the meeting at Beirut. It is hoped that they will be able to visit all the principal sites of archæological interest including Byblos, Sidon, Baalbek, Palmyra, Tiberias, Beisan, Megiddo, Jerusalem, and Jerash. After the close of the Congress on April 23, a visit will be paid to Petra, lasting from April 24 until April 28.

WE have received the third number of *Brighter Biochemistry*, the illustrated journal of the Biochemical Laboratory, Cambridge. It maintains the high standard of humour reached by its predecessors Although the topical allusions have mainly a local sign, yet any one who is acquainted with the work of this School can derive great enjoyment from them The illustrations both in the case of past and present personages are, we hope, rather legendary than actual portraits. In the section entitled "Dunnsday Boke" readers will find a full account of the manners and customs of the community. Copies, 2*s*. 6*d* each, may be obtained from the editors at the Sir William Dunn Institute of Biochemistry, Tennis Court Road, Cambridge.

THE first photographic lens interferometer, designed and made by Messrs. Adam Hilger, Ltd., and supplied to a British firm, is now installed at the Leicester works of Messrs. Taylor, Taylor and Hobson, Ltd., for the testing and control of their optical designs and products. The first problem which the research staff of the firm had to solve was to eliminate mechanical strains introduced by ordinary methods of mounting the component glasses. Such strains have been found in high-class anastigmats of all makes, and though slight in themselves, they introduce considerable want of symmetry in the interference patterns. The strains can be eliminated by a simple geometric mounting of the component lenses, for which Messrs. Taylor, Taylor and Hobson have applied for patent protection. The firm hopes to exhibit the system at the forthcoming Optical Convention.

MR. HERBERT SPENCER'S trustees are publishing through Messrs. Williams and Norgate, Ltd., an addition to Herbert Spencer's "Descriptive Sociology." The work, which will deal with Ancient Egypt, has been written by Sir Flinders Petrie and will be issued at an early date.

AMONG the spring announcements of the Cambridge University Press are "Science and the Modern World," by Dr. A. N. Whitehead, which embodies a study of the mentality of successive epochs during the past three centuries in so far as it has been influenced by the development of science; "The Quantum Theory of the Atom," by G. Birtwistle, dealing with the evolution of the quantum theory from its inception by Planck down to the most recent work on the reaction of the atom to radiation fields; and "Population Problems of the Age of Malthus," by G. Talbot Griffith, being a study of economic conditions and their effect on the birth, marriage, and death rates at the time when Malthus wrote his "Essay on Population."

APPLICATIONS are invited for the following appointments, on or before the dates mentioned: Inspectors under the Ministry of Agriculture and Fisheries for the purposes of the Diseases of Animals Acts, 1894 to 1925—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S.W.1 (February 15). A tutor and lecturer on methods of teaching science (especially physics and chemistry) at the London Day Training College—The Principal, London Day Training College, Southampton Row, W.C.1 (February 22, on Form H.2/1). A Vice-Principal of the Somerset Farm Institute, Cannington, near Bridgwater—The Principal (February 22). A senior lecturer in the department of logic and metaphysics of the University of Glasgow—The Secretary, University Court, the University, Glasgow (February 24). A secretary to the Royal Horticultural Society—The Treasurer, Royal Horticultural Society, Vincent Square, S.W.1 (February 27). A man to take charge of the A.I.D. Chemical and Physical Testing Laboratory at the R.A.F. Stores Depot, Kidbrooke, S.E.—The Secretary (S.2), Air Ministry, Adastral House, Kingsway, W.C.2.

Our Astronomical Column.

RECENT SUNSPOT AND MAGNETIC "STORM."—On January 26, the largest magnetic disturbance for five years was recorded by the magnetographs at the Royal Observatory, Greenwich. The disturbance commenced at 16¼h., rose to a considerable maximum, and subsided soon after 5h. on the following morning. The greatest range shown during the disturbance by the magnetic needle recording magnetic Declination was one degree. The photographic traces of North Force and Vertical Force also showed considerable deflexions. Press telegrams announced a remarkable display of the aurora borealis seen from Norway and North America on the night of January 26.

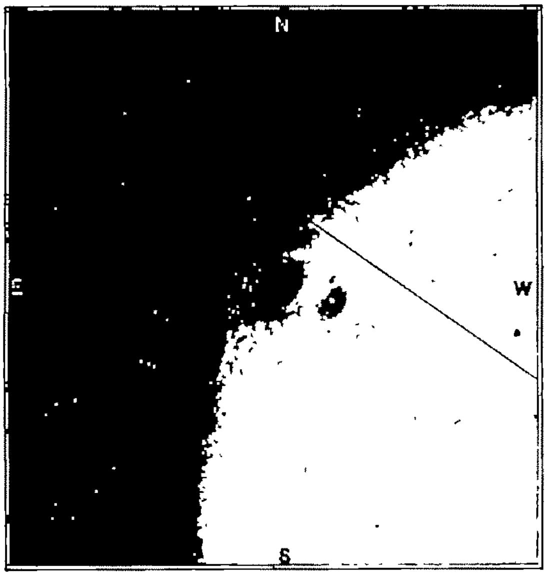

FIG 1.

At the time of commencement of the magnetic "storm," the great spot, which had been a prominent object on the sun's disc since January 18, was about 27° west of the central meridian. The spot was first seen from December 22 to January 3, when it was also of great size, but no disturbances of any consequence were recorded by the magnetographs during this period. Mr. J. Evershed, observing with his spectroscopic instruments at Ewhurst, Surrey, noted large disturbances in the chromosphere over the spot when seen close to the west limb on January 4 (R.A.S. report, *The Observatory*, February 1926).

The accompanying photograph (Fig. 1) was taken on January 20 at the Royal Observatory, Greenwich, and shows the large spot (latitude 22° N.) two days after its reappearance on the sun's disc. The spot is followed by bright faculæ in which a few scattered spots can be seen. Preceding the great spot by 9° of solar longitude is a smaller one, which has formed whilst this part of the sun was turned away from the earth. It is probably separate from the great spot disturbance, but the Mount Wilson polarity determinations will throw light on this point.

Details of position and area of the large spot will be found in NATURE of January 9 and 30.

PHOTOGRAPHIC STELLAR PHOTOMETRY.—The application of photography to stellar photometry has at present scarcely progressed beyond the experimental stage. Various methods have been used by different observers, and it is therefore of some interest to receive details of those in use at the Yerkes Observatory, as described by J. A. Parkhurst and Miss Farnsworth in the *Astrophysical Journal*, vol. 62, p. 179. The stellar images were taken in sharp focus, and were compared in a Hartmann microphotometer with an artificial scale of images, formed at equal intervals of about half a magnitude by giving a series of exposures, in logarithmic ratios, on a chosen star. The scale values were obtained independently on each plate by using coarse wire objective gratings, and comparing the first order spectra obtained in this manner with the central image. Both photographic and photovisual magnitudes were measured—the latter by using Cramer isochromatic plates with colour filters. The reduction to international magnitudes was effected either by means of duplicate exposures and comparison with stars of the North Polar Sequence, or indirectly by comparison with Harvard or Potsdam stars included on the same plate, reducing the latter magnitudes to photographic by correcting for colour index. The results of this work during 1914–1924, together with further details, are promised in a forthcoming publication of the Yerkes Observatory.

Research Items.

EARLY MAN IN RUSSIA.—In a recent number of the Russian *Anthropological Journal*, Prof. A. P. Pavlow, of Moscow, records the discovery of the fronto-parietal portion of two human skulls in a Pleistocene deposit near the village of Oundory, on the lower Volga. He describes them as in the same mineralised condition as the bones of the mammoth, woolly rhinoceros, reindeer, camel, and other Pleistocene mammals with which they were associated A human humerus, in the same state of preservation, was found with them. The brow-ridges in the skulls are not strongly marked, and Prof. Pavlow concludes that the new specimens may be referred to the same race as the skulls from Combe-Capelle, Brünn, and probably Prĕdmost He thinks the much-discussed skull from Galley Hill may be placed with them.

A CEREMONIAL "MASK" FROM NEW GUINEA.—In *Man* for January, Mr. T. A. Joyce figures a remarkable ceremonial object of indeterminate use from the Sepik River. It is here called a mask, a similar object having been described by Otto Reiche ("Ergebnisse der Südsee Expedition 1908–10," vol. 2, Pt. 1, p. 401) as the earliest form of mask, but no details as to its use were given. The present example has been presented, with other objects, to the British Museum by Mr. Schreibner of Dutch New Guinea. It shows no attachments suitable for a human head such as would be necessary for a mask. It resembles a shield, long-oval in shape, and is composed of basket work, of coiled technique, supported by a stout rim of split bamboo, and has a kind of "backbone" consisting of a wooden stick fastened to the reverse surface in a longitudinal section. The face is plastered with clay in which the ornamentation is set. At the top is a human skull secured by cane lashings, ornamented with cowrie shells, and furnished with a long artificial nose, similarly decorated. Below the skull are semicircular rows of shells and pigs' tusks simulating a necklace. The rest of the surface is decorated with series of pigs' tusks, coix seeds, crocodile teeth, fragments of shell, and two broken bits of china. The rarity of ethnographical specimens from the Sepik River gives these objects an exceptional interest.

THE REGIME OF THE NILE.—In a large and well-illustrated monograph on the Lake Plateau Basin of the Nile (Ministry of Public Works, Egypt, Physical Dept. Paper No. 21), Dr. H. E. Hurst makes some interesting additions to our knowledge of the origin of Nile water. From December to May the White Nile is the main source of Nile water, contributing in April so much as 80 per cent. In flood time, however, the Blue Nile may contribute so much as 72 per cent. and the Atbara so much as 26 per cent. Of the two streams of the White Nile, the Bahr el Gebel is more important than the Sobat. From early April to the middle of July the former supplies 50 per cent. of Nile water. Taking into account the time of travel of the water, it appears that the period of low water at Aswan, mentioned above, corresponds with November 8 to February 25 at Mongalla in the Sudan. Gauge measurements have shown that the contribution of the lake sources during that time is about 94 per cent. of the discharge of the Bahr el Gebel. The corresponding time at the tail of the swamps and the Sobat mouth is February 22 to June 11, when the discharge from the swamps is 73 per cent. of the total White Nile discharge. At Khartoum, where the critical period begins about a month later, the White Nile contributes about the same percentage of the total discharge. Hence Dr. Hurst calculates that during the period of water shortage in Egypt, nearly 50 per cent. comes from the equatorial lakes. This gives them a somewhat greater value to Egypt than was formerly accepted.

MOLLUSCA FROM THE MOLUCCAS.—A "Report on a Collection of recent Shells from Obi and Halmahera (Moluccas)" and surrounding islands, by Dr. C. H. Oostingh, has been published by the Geological Institute of the Agricultural University, at Wageningen (Communications, No. 9). It is a bulky list of just on 300 species almost exclusively marine, without descriptions, but with ample and properly compiled synonymy (which is rare) and distribution for each. It is further accompanied by an excellent and full bibliography giving the most recent information as to the dates of publication of the more important works cited Any one, therefore, working at the fauna of the region in question will find the work indispensable, whilst probably wishing that the little outline map of the Moluccas on p. 5 had been commensurate in value with the rest of the volume, and that an index to the genera had been added, since there is no hint given as to whose classification, if any one's, has been followed: it cannot be a very recent one since the pearl oyster has been left in the genus Pteria, from which it has long been removed.

CARIDEA IN THE INDIAN MUSEUM.—Dr. Stanley Kemp, in his concluding (seventeenth) note on Crustacea Decapoda in the Indian Museum (*Records Ind. Mus*, vol. 27, Pt. iv, 1925), brings together observations on members of eight families of Caridea, and provides synoptic tables, where necessary, of the characters of the genera and species. In addition to matters of taxonomic interest, the author directs attention to the occurrence in females of the genus Leptochela of dimorphism correlated with the breeding season. All the females with a tricarinate carapace were found to be either ovigerous or to have just liberated their young. The females with smooth carapace were not ovigerous, and showed no sign that they had recently borne eggs Dr. Kemp concludes that the female moults immediately before the extrusion of her ova, the carapace in the course of this moult developing longitudinal carinæ After the eggs have hatched, another moult occurs and the carapace resumes its original smooth condition. Dimorphic females have been found in three species, and it is not unlikely that they occur throughout the genus. The occurrence of luminous organs in two shallow-water genera of Pandalidæ is noteworthy, as such organs have hitherto been known among Caridea in deep-sea species belonging to the family Hoplophoridæ. The discovery of a species of Palæmonetes in a lagoon and in a backwater in south India is interesting, as no member of this genus was known between Mesopotamia and the coasts of China. Dr. Kemp suggests that the marked discontinuity in the distribution of the genus is more apparent than real, for this is an inconspicuous animal which will no doubt be found in many additional localities.

THE ORIGIN OF THE BANANA IN AMERICA.—The question of the original home of the banana has given rise to much difference of opinion, though most botanists have assumed that it lay in the Indo-Malayan region. It has been suggested that the banana was introduced into America by way of the Canary Islands and Hayti about the year 1516. However, a few early writers, such as Humboldt, have pointed out that it was cultivated along the Orinoco and Beni rivers by the aborigines at the time of their first exploration. There is, therefore, historical evidence that the banana was indigenous in America. Dr E. W. Berry has now been able to throw fresh light on the problem by the identification and description of fossil banana seeds from Tertiary beds in Colombia (*Am Journ Sci*, Dec 1925) The exact horizon cannot as yet be stated, but Dr Berry favours an Oligocene age The independent cultivation of the banana by the natives of America long before the advent of Europeans thus appears to be proved, though it cannot yet be argued that South America was the actual region of origin.

Parasitism of the Dodder.—At the present time when there is so much controversy on the rôle of xylem and phlœm in the transport of food in the plant, there is renewed interest in the method by which a total parasite like the dodder attaches itself to its host, as presumably this connexion must provide for the transport of food materials from host to parasite. Considerable interest therefore attaches to the conclusion reached by John Thomson (*Trans. of the Roy. Soc. of Edinburgh* 54, Part II No 5) that in the sucker of the dodder no phlœm whatever accompanies the xylem and penetrates into the host tissues. This conclusion is directly at variance with the earlier conclusions of Peirce and Thoday (Sykes) (*Annals of Botany* 1893 and 1911), but it is in complete agreement with a recent paper by Zender (Inst de Botanique, Université de Genève, Series 10 Fasc 8, 1924), and there seems little doubt that the earlier observers, who were not in agreement as to the position of the phlœm, were in error in reporting its presence. Thomson's further conclusion that the sucker makes little or no special attachment to the phlœm is surprising even for the one species he has examined, *Cuscuta reflexa* (Roxb), in view of the very special haustorial-like attachments to the phlœm described and figured by Zender in other species; but continental work on the anatomy of Cuscuta is somewhat neglected in Thomson's paper, and in the absence of any comparison of technique and results by the latter author, it is difficult to reconcile the discrepancies between the two accounts of the union between parasite and host.

Oxygen and Root Growth —*Publication No. 368* by the Carnegie Institution, upon the "Physiological Features of Roots," by William Austin Cannon, gives good reasons for introducing two new terms into the consideration of the oxygen relation of roots. The least oxygen partial pressure at which root growth is observed is termed the lower critical concentration and is valid only for a given species when growing at a given temperature, similarly an upper critical pressure is defined, which is the minimal oxygen pressure at which, at the given temperature, normal growth can take place. The oxygen demands of the root system increase very greatly with rising temperature, and while both these critical concentrations may be low for low temperature, at high temperatures the upper critical pressure in particular rises considerably. For many plants the range between upper and lower critical pressures may be very considerable, and represents a range, therefore, over which oxygen concentration is considerably limiting root activity. Whilst for some very aerobic root systems the higher critical concentration at high root temperatures may practically approximate to the normal oxygen content of the air, other root systems, like those of Salix and species of Baccharis, etc , may show a much lower upper critical concentration and continue to grow at very low oxygen concentration indeed. Another interesting feature of this monograph is a chapter contributed by Edward Elway Free upon experiments with small oxygen concentrations in which helium was used as an inert diluting gas to see if nitrogen could safely be treated as without action save as diluting the oxygen. At first experiments seemed to indicate that the nitrogen was more toxic than the helium to the root systems; this difference disappeared, however, when both gases were completely freed from oxygen, and it turned out that small oxygen concentrations seemed more readily available to the root system when the diluting gas was helium. This effect is traced with great possibility to the greater density of the nitrogen, which leads to the result that the small oxygen content is diffusing much more rapidly to the root surface through helium than through nitrogen.

Magnetite Garnet Rocks from Adelie Land — In the Scientific Reports of the Australian Antarctic Expedition (Series A, vol. 3, Geology, Pt. 5. Sydney, N S.W.: Alfred James Kent, 1925. Price 2s), A. L. Coulson describes a series of schists and gneisses collected from the glacial moraines of Cape Denison. The specimens are characterised by an abundance of either magnetite or garnet or both. About half of them—containing dominant magnetite—correspond closely with Grubenmann's Group XI. of the crystalline schists Others, however, contain garnet and magnetite in roughly similar proportions, together with quartz, felspar, and biotite, and their chemical characters are widely different from those of any group of schists hitherto defined It is suggested that these new types of garnet-magnetite rocks are probably derived from sediments the composition of which has been modified by igneous emanations. As the garnet is an aluminous variety, it seems probable that the original sediments were argillaceous, for in the analogous skarn-rocks of Scandinavia derived from limestones, the characteristic garnet is andradite That igneous emanations have played an important part in the development of the series is further suggested by the occurrence of a specimen containing abundant tourmaline This rock is also rich in cordierite containing well-formed pleochroic haloes, and its mineral assemblage indicates beyond doubt that it is a sedimentary derivative The petrological history of the whole assemblage of specimens has been clearly and convincingly elucidated, and the report is a valuable contribution to our growing knowledge of Antarctica.

The Measurement of Geological Time.—At the annual meeting of the Lake Superior Mining Institute on August 13 last, Prof. A. C. Lane presented the report of the Committee of the National Research Council on "The Measurement of Geological Age by Atomic Disintegration" Apart from the very careful work of Ellsworth in Canada, no very definite results have yet emerged, most of the active members being still engaged in developing methods. An example of one of the most promising of these is the concentration of the radioactive minerals, such as zircon and allanite, from a Palæozoic pegmatite near Boston. By a further concentration, allanite alone was separated, and its analysis by Ellsworth yielded a lead-ratio, Pb/(U + 0·354Th), of 0·043, a definitely Palæozoic ratio. Another new result is a ratio of 0·084 from an analysis of polycrase from Brazil by E. P Henderson. This agrees fairly well with results on presumably late pre-Cambrian minerals from Central Africa and Ceylon. The Committee has in hand further work which will enable an age comparison between Keweenawan and pre-Huronian granites to be drawn. It is pointed out that the most pressing needs are to test the hypothesis of Kirsch that thorium may be derived from "thorio-uranium," and to discover whether consistent lead-ratios can be obtained from minerals rich in thorium. The evidence at present available, and already discussed by Holmes and Lawson, does not support the Kirsch hypothesis, but suggests that thorium minerals tend to lose part of their lead just as all radioactive minerals necessarily lose part of their helium content. The Committee is to be congratulated on laying the foundations of this comprehensive research cautiously and securely. In its next report it should be able to clear up much of the present confusion of ideas due to the competition of conflicting hypotheses.

OPTICAL GLASS MANUFACTURE.—Interesting biographical details of Pierre Louis Guinand (1748–1824), who played an important part in the early development of the art of making optical glass, are given by M. Paul Ditisheim in the *Bulletin de la Société Astronomique de France*, April 1925. The advances in optical designing made by Moor Hall, by Dolland and by Ramsden had produced a demand for homogeneous pieces of flint glass of much larger size than had been previously required. The prolonged and laborious investigations of Guinand were largely responsible for enabling this demand eventually to be met. The methods he adopted are still considered essential in the present-day manufacture of optical glass. After developing his process at Les Brenets, in Switzerland, Guinand was engaged in 1805, by Reichenbach and Utzschneider, a firm of instrument-makers, to establish a glass factory at Benediktbeurn near Munich. Here he worked for just over eight years, producing glass for more than 5000 achromatic objectives. He worked in conjunction with Fraunhofer, whom he had instructed in the process of glass-making. Fraunhofer was put in charge of the works in 1811, and two years later Guinand returned to Les Brenets, where, with his son Aimé, he recommenced manufacture. In 1823 he placed at the disposal of the Astronomical Society of London a disk of flint glass of 7½ in. diameter. This was worked and mounted by Tulley, a London optician, and its performance called forth unstinted praise from Dolland, John Herschel and other members of the Society. Guinand died in 1824. In 1828 his son Henri, in partnership with G. Bontemps and others, introduced his processes into France. In 1848 Bontemps entered the service of Messrs. Chance Brothers of Birmingham, who were thus enabled to compete with the French firms, and have since then uninterruptedly continued the manufacture of optical glass.

A PHOTOGRAPHIC SPECTROPHOTOMETER FOR THE ULTRA-VIOLET.—A method of measuring the rotatory power of liquids for ultra-violet rays is described by Messrs. A. Cotton and R. Descamps in the *Comptes rendus Acad. Sci. Paris*, Jan. 4. Light which has passed through the polariser, a trough containing the liquid and the analyser, along an axis *xx*, is deflected at right angles to this axis by a train of prisms. It falls on a photographic film bent into a cyclindrical form with *xx* as the axis of the cylinder, forming upon it a series of images of a short slit for the different ultra-violet lines of the mercury arc lamp employed for illumination. The analyser and the train of prisms are mounted together, so that they form a system which can be rotated about the *xx* axis. The light spots move over the photographic plate, which registers their intensities for different positions of the analyser, making it possible to determine the angle at which each of them is extinguished. In the instrument as constructed, the first prism of the train also acts as the analyser, being made of Iceland spar; the second prism is of quartz, and the necessary lenses and the trough walls are transparent to ultra-violet rays.

BLACK AND WHITE GLOBULAR LIGHTNING.—In the *Comptes rendus Acad. Sci. Paris*, Jan. 4, M. E. Mathias collects accounts of a number of cases where non-incandescent bodies were seen to explode, in some cases causing injury or death. These balls of globular lightning were black, white or grey, and in the opinion of the author were due to a ball of ordinary globular lightning, the incandescence of which was hidden by a mantle of cloud or smoke, which in some cases clung to the surface of the ball, and in others formed a torn mantle around it. It is suggested that this smoke was due to the actual burning by the incandescent mass of organic substances such as cellulose. In one case, described by Zurche and Margollé, a number of luminous balls, and also grey balls, were seen to emerge from a waterspout or "tornado" at d'Arsonval (Pas-de-Calais), both kinds exploding with a loud detonation, sending out pieces of branches which the tornado had torn from the trees. The clinging mantle sometimes formed is ascribed to electrostatic attraction between the incandescent centre and the surrounding smoke.

DETERIORATION OF ALUMINIUM ALLOYS.—From time to time Prof. Ernest Wilson has communicated to the British Association the results of exposure tests made at King's College, London, on a series of light aluminium alloys in the London atmosphere. The experiments, which have been in progress for twenty-four years, are now brought together in a paper published in the *Journal of the Institution of Electrical Engineers* (No. 347). Aluminium alone, or alloyed with copper or with copper and manganese, shows a steady deterioration in electrical conductivity throughout the period, whilst the alloys containing copper and nickel, copper and zinc, or copper, nickel and zinc, often show a decided increase in conductivity after periods varying from five to ten years. The specimens kept in the laboratory for control also exhibit a small increase, and this process may be accelerated in the exposed specimens, or possibly the differential corrosion may have the effect of removing some of the impurities. The alloys containing copper and nickel are remarkable for their permanence, some of them being almost as good mechanically as when new. A microscopical examination would perhaps throw light on the nature of the changes which affect the conductivity, there being evidently a change of an internal kind which is distinct from the diminution of conductivity due to corrosion.

CONDUCTIVITIES OF HYDROGEN AND POTASSIUM CHLORIDE.—The *Journal of the Chemical Society* for December contains an account of the electrical conductivities of hydrogen chloride and potassium chloride in water and water-acetone mixtures, by T. K. Brownson and F. M. Cray. The measurements were made with great care and the results are of importance, since accurate work in the region of non-aqueous solvents is not too abundant. A minimum conductivity (equivalent) with hydrochloric acid was found with solvent containing 85 per cent. of acetone, and a minimum equivalent conductivity of potassium chloride was found with solvent containing 40 per cent. by volume of water. The Ostwald dilution law does not hold fully in any acetone-water mixture investigated, but as the acetone content increases it gives values more nearly approaching a constant at all dilutions.

Annual Report of the Smithsonian Institution.

THE annual report of the Secretary of the Smithsonian Institution, which was submitted to the recent meeting of the Board of Regents, revealed a wide range of activities for the year. The scientific expeditions in which the Institution took part penetrated into many corners of the earth. After researches extending over six years, Dr. Walcott discovered fossils in the Lyell limestones of the Canadian Rockies which fixed the limestones as of Upper Cambrian age. In China the Institution's zoological collecting expedition under the auspices of Dr. W. L. Abbott collected 50 boxes of insects, birds, mammals and reptiles, in spite of the murderous Bolotsi aborigines who infest the Province of Szechwan. Another expedition in China, under the direction of Mr. C. W. Bishop of the Freer Gallery of Art, Smithsonian Institution, examined a number of large mounds, including two tombs of the Han Dynasty (206 B.C. to A.D. 221). The work brought to light Chinese cultural objects dating from prehistoric times to the Han period, including stone axes, jade chisels, chariot fittings, mirrors.

In Panama and Costa Rica the Smithsonian botanical expedition under Mr. Paul C. Standley collected material for a report on the plant life of these little-known areas. Mr. John L. Baer, Smithsonian anthropologist, lost his life while with the Marsh expedition in Panama.

The Bureau of American Ethnology, which grew out of Smithsonian work begun in 1850 and is still directed by the Institution, conducted a number of important researches among the American Indians. The aboriginal Indian culture is fast disappearing, and every effort is made by the Bureau to secure as much as possible of this ancient lore before it is lost for ever. The Chief of the Bureau, Dr. J. Walter Fewkes, brought to light some rare copper ornaments while excavating mounds near Muscle Shoals, Alabama, which will be submerged when the Wilson Dam is completed. Dr. Fewkes also directed repair work on the tower of the famous "Mummy Cave House" in Arizona, one of the finest examples of primitive architecture in the south-west. Mr. J. P. Harrington continued his work of excavation of the Burton Mound Indian village, Santa Barbara, California. Large collections have resulted from his work, and Mr. Harrington is preparing for publication a monograph on the archæology of this interesting region. Miss Frances Densmore continued her researches in Indian music; the original phonograph records by means of which she obtained these songs from the Indians are preserved by the Bureau.

The year has been a most important one in the researches carried on by the Astrophysical Observatory of the Institution. Four papers were published during the year which summarise the work of the Observatory during the past twenty years on the sun's radiation and its connexion with weather on the earth. Experimental forecasts based solely on the variations in the solar radiation have been continued for the City of New York. These are still largely experimental, and the staff of the Observatory is now engaged in revising the methods of measuring and recording the sun's radiation. The observatory station on Mt. Harqua Hala, Arizona, has been removed to Table Mountain, California, to obtain better atmospheric conditions

The National Museum, another outgrowth of Smithsonian activities, which the Institution still directs, received during the year more than 350,000 new specimens. Among the most interesting of these were a series of slabs from the Grand Canyon containing a splendid series of fossil footprints; casts of certain of the famous finds of primitive man; and collections of California Indian baskets, insects from the late Colonel Thomas L. Casey, and mineral specimens, including axinite crystals, from Colonel Washington A. Roebling The Fukushima Company of New York has loaned for exhibition to the Museum a crystal ball weighing 110 pounds and measuring 13¼ inches in diameter, which is said to be the largest of its kind known.

The attendance at the National Zoological Park again exceeded all previous records, the total reaching 2,518,265 Mr Victor J. Evans made the outstanding gift of the year in a young male chimpanzee.

The report also directs attention to the urgent need of a suitable building to house the National Gallery of Art, which is now crowded in the National Museum to the detriment of the art and museum exhibitions. Congress has already provided a site in the Smithsonian park for a building, and through private subscription 10,000 dollars has been obtained for the preparation of preliminary plans.

The International Exchange Service, created by Secretary Joseph Henry, for the interchange of scientific and governmental documents with foreign nations and learned societies, handled during the year a total of 468,731 packages. A total of 2325 boxes of publications were sent to 64 foreign countries.

Owing to financial difficulties encountered by all international enterprises since the War, the International Catalogue of Scientific Literature, of which the Smithsonian administers the United States Regional Bureau, has not yet resumed publication of the seventeen annual volumes formerly published. Smithsonian publications reached a total of 155 volumes and pamphlets for the year. Of these the Institution proper published 68 items. The total of copies distributed reached 171,865.

In discussing his annual report, Dr. Walcott directed attention to the fact that the past year has marked a crisis in the financial affairs of the Institution. He pointed out the disparity between the extent and magnitude of the research and publishing activities of the Smithsonian Institution and its annual income of 65,000 dollars. Only 6000 dollars of this sum has been available for research and explorations, and the Institution has only been able to carry on the quantity of work done through the generosity of private individuals. In spite of this generosity, the Institution's publications have been reduced to a third of what they were before the War, and some series, such as the "Contributions to Knowledge," have been suspended altogether. Furthermore, the Institution has been unable to embark upon the larger projects in fundamental research which have been typical of its past history.

For these reasons the Institution has determined on several steps to increase its resources. One of these is to issue a series of popular scientific books to be known as the Smithsonian Scientific Series, similar in plan to the Chronicles of America series, issued by the Yale University Press. Another plan has been recently announced to the public in the nature of an appeal for an addition of 10,000,000 dollars to the Smithsonian's endowment. The decision to go before the American people has been made because of the fruitfulness of the original bequest of the Englishman, James Smithson, who founded the Smithsonian, because of the Institution's position as the pioneer of American research, because of the national scope of its activities and the national character of the benefits it confers in "the increase and diffusion of knowledge."

Research at the University of Sydney.

THE various centres engaged in productive scientific work are continually confronted with the problem of how best to bring the results to the notice of their colleagues. In chemical circles there seems to be a great effort made to confine publication, in the main, to certain well-known journals, to which all chemists will then naturally turn. So long as other channels exist for the chemical "cubist" to express himself in the possibility that he may be the conservative leader of the chemical theorists of the next generation, this is possibly a practical solution, at any rate for the countries where science is now well established.

Overseas universities and research centres frequently adopt the plan of issuing the work of their members, either as reprints from journals, or in local publications, and circulating this to other centres throughout the world with the view of receiving other publications in exchange. Such exchanges are probably growing in favour as a method of building up a library. The University of Sydney began thus to issue reprints in 1894, and in 1922 it much enlarged the scope of the scheme, deciding to issue these reprints in various sections dealing with different subjects. A number of these volumes has recently reached us, and though we cannot attempt a complete survey of their contents, we are glad to direct attention to a few of the valuable papers in them.

Series 6 is devoted to geological and geographical papers and vol. 1 includes twenty memoirs, by members of the staff and scholars of the University, mostly on the geology of New South Wales. The paper of most general interest is the lecture by Sir Edgeworth David on the antiquity of man in Australia, with special reference to the Tasmanians. He adopts the view that the Australians and Tasmanians come from different stocks, and in reference to the Talgai skull quotes Sir Arthur Keith's view that it is Tasmanian in affinity, though that view is not expressed in Sir Arthur Keith's last discussion of this skull. Prof. Griffith Taylor's presidential address to the Geographical and Historical section of the Australasian Association discusses the bearings of Australian geography on national problems, and adopts the conclusion that owing to the ethnologic superiority of the Chinese to the European, their entry and intermarriage with the Australians would improve the stock. Prof. Benson discusses the correlation of the Australian Carboniferous with the European, and remarks that the Burindi Series has some Viséan affinities. Prof L. A. Cotton describes the Kurrajong earthquake of August, 1919. Mr. W. R. Browne, in addition to a paper on igneous rocks in South Australia, gives a valuable account of the petrology of the country around the Broken Hill mining field. G. D Osborne and W. R. Browne describe a beautiful glacially striated pavement of Carboniferous age in New South Wales.

The first volume of Series 9 (Medical Sciences—Non-clinical) of the "Sydney University Reprints" consists of a number of papers most of which have appeared in various publications such as the *Journal of Anatomy*, the *Australian Medical Journal*, and the like. One, dealing with the diet of the Australians, by Dr. H. S. Halcro Wardlaw, is an official publication of the New South Wales Board of Trade. Dr. Wardlaw has also reprinted here a valuable paper on the energy consumption of Australian students. Among these contributions to science by members of the University of Sydney, which range in date from 1921 to 1924, we welcome several by the late Dr. J. I. Hunter, whose premature death has been a great loss to science; these include a study of a Neanderthoid Australian skull, written in conjunction with Mr. A. St. N. Burkitt, and a further contribution to the controversy on the relation of the Piltdown jaw and cranium, in which he reviewed Dr. Hrdlička's conclusions, which were largely based upon a study of the teeth, and gave a brief forecast of the results of the reconstruction at which he and Elliot Smith had arrived in their joint study of the cranium The paper on the Neanderthoid Australian skull mentioned above is worthy of special attention, as it is not so well known as it deserves. The skull was that of a female and showed a remarkable combination of primitive character in the cranium, combined with more delicate characters in the facial region, which was both orthognathic and leptorrhine. It had an enormous development of the supraciliary ridges, and glabella, a well-developed bregmatic eminence, and a marked development of the torus occipitalis. Added to these primitive features was an extremely low sloping forehead, while the maximum occipital point coincided with the inion. Certain features showed a resemblance to Pithecanthropus.

Vol. 1 of Series 12 (Social Science—Economics, Education, History, Philosophy, and Psychology) contains ten reprints, all short, varying from three to twenty-four pages, but there is no shame in brevity and these scholarly little articles are a valuable contribution to general philosophic and psychological knowledge Among so many varied papers it is difficult to make a selection for special note. Some of the articles are more descriptive, others more constructive, and high in the first category comes Prof. E. E. Anderson's stimulating account of "The Present Religious Situation"—a careful consideration of the nature of religious development. Sir John Macpherson's analysis of "The Influences which cause Fluctuations in the Production of Insanity" shows the enormous complexity of the subject, and the need for careful scrutiny of seemingly accurate statistics, and Prof. B. Muscio shows his characteristic originality and freedom from scholastic bias in his thoughtful contribution on "The Meaning of Philosophy." These reprints bear the same relation to the usual scientific treatise that a magazine of short stories bears to a novel, and, like a magazine, the volume is pleasantly readable

Vol. 1 of Series 13 consists of twenty-three papers published in various journals during the years 1920–1924 by workers in the Department of Zoology of the University of Sydney. The series includes the late Prof. W. A. Haswell's last two papers—on Astacocroton—a new type of acarid parasitic on the gills of crayfishes, and on the structure of the proboscis of the syllid worms, and two papers by Prof. L. Harrison on the breeding habits and the pigmentation of the eggs of some Australian frogs. Mr. E. A. Briggs, lecturer in zoology, contributes two papers, one of which describes in detail a new species of crawling medusa, and Miss E. E. Chase, demonstrator, gives an account of a new avian trematode. The two Macleay fellows of the Linnean Society of New South Wales, Miss M. Henry and Miss V. Irwin-Smith, are responsible for the remaining papers. Four by Miss Henry are contributions to a monograph of the fresh-water Entomostraca of New South Wales, and those by Miss Irwin-Smith are accounts of nematode worms, especially from lizards, and of the life-history of brachycerous Diptera. The Department of Zoology in Sydney has from its institution played a worthy part in scientific research, and the volume affords good evidence that no time was lost after the conclusion of the War in resuming investigations.

Vol. 1 of Series 2 contains botanical papers published between 1921 and 1924. To the botanists in a new country falls the duty of widening our horizon as to botanical conditions, and these papers are valuable examples of such literature. They include ecological studies of Australian vegetation by Marjorie I. Collins, of mangrove and salt marsh vegetation and arid and semi-arid regions; studies of Australian parasitic flowering plants, and of Australian examples of symbiosis (mycorhiza and root-nodules) by J. M'Luckie, also notes upon the life-history and structure of Australian Phanerogams and ferns by Prof. Lawson, P. Brough, and Jessie Steele. M. M. Williams has a brief note upon interesting brown seaweeds, including the one apparent parasite in the group, *Notheia anomala*.

Series 11 covers mathematics, physics, and astronomy, and vol. 1 contains seven papers dealing mainly with physical questions. They show that the University is not restricting its research work to the industrial problems which arise in the colony, but is taking its part in the solution of scientific questions the interest of which is world wide. Mr. E. H. Booth deals with the ions produced in air which has bubbled through water, a process which bears on the problem of how the earth maintains its negative charge. Dr. G. Harker shows that the vapour arising from a boiling solution has a temperature higher than that from the pure solvent boiling under the same conditions. Prof. Carslaw solves a problem on the cooling of a sphere with a core and shows that in the Mathematical Tripos of 1904 the candidates were asked to prove something which was untrue, while a paper by the late Prof. Pollock gives an interesting account of the physics of the stethoscope.

Vol. 1 of Series 3 is a collection of papers published in the various chemical journals by workers in the chemistry departments of the University. These show that research work is being actively prosecuted. Physical chemistry measurements include those of the molecular solution volumes of various organic substances in ethyl alcohol, which show that several of the solutes are associated in the liquid state; the development of the miscibility tests for eucalyptus oils in which the oils are added to methyl alcohol-water mixtures and the critical solution temperatures determined; the decrease in the values of the reaction constant in the decomposition of hydrogen peroxide by colloidal platinum when different concentrations of protective colloids are added, and the action of soaps as protective colloids for gold hydrosols, in which it is shown that although the stabilisation is very pronounced the coagulating influence of the sodium ion of the lower soaps begins to outweigh the protective action. A number of the reprints deal with organic chemistry: the preparation of organic compounds of arsenic of the type $R_1R_2R_3As$, $RAsI_2$ where R_1R_2, etc., indicate similar or dissimilar alkyl or aryl groups; studies in the formation of ring compounds by condensation of aromatic amines and diketones, etc.; researches on the phellandrenes and a number of contributions to the chemistry of piperitone. In addition, investigations have been carried out on the active principle of trees of the kind to which belong the dreaded "ordeal" or "doom tree" of the African pygmies.

Voltaire and Medicine.

In the second part[1] of his paper on "Voltaire and Medicine," read before the Section of the History of Medicine of the Royal Society of Medicine on December 16, the president, Dr. J. D. Rolleston, gave some account of Voltaire's allusions to anatomy and physiology, his advocacy of inoculation against small-pox, and his interest in the history and ravages of syphilis, a knowledge of which he had derived from Astruc's work on venereal diseases. He also referred to the attention paid by Voltaire to other matters connected with public health, his acquaintance with medical jurisprudence and particularly his sceptical attitude toward historical cases of poisoning, in many of which he showed that death was more probably due to some acute infection, and his remarks on various diseases of social importance, such as mental disorders, convulsive hysteria at the tombs of saints and ecclesiastics, alcoholism and the King's evil.

Several passages in his works show that Voltaire had paid some attention to anatomy. He commences his article on "Man" in the "Dictionnaire Philosophique" by saying that in order to learn the physical aspects of the human race, one must study works of anatomy or the article of M. Venel in the "Dictionnaire Encyclopédique," or rather follow a course of anatomy. In his article on "Anatomy" in the same work, he remarks that "Ancient anatomy bears to modern anatomy the same relation that the rough geographical charts of the sixteenth century do to the topographical maps of to-day." In the "Histoire du Docteur Akakia" Maupertuis is condemned for his advice to neglect anatomy. Voltaire, however, fully realised that much was yet learned in human anatomy. In Chap. 35, entitled "Incertitudes en Anatomie" of the essay "Des singularités de la nature," he exclaims, "In spite of all the help that the microscope has given anatomy, and in spite of the great discoveries of so many skilful surgeons and physicians, what interminable discussions have arisen, and in what uncertainty we still remain!"

Although physiology was still in its infancy in the eighteenth century, Voltaire seems to have been well abreast of the knowledge of his time. In the "Dictionnaire Philosophique" he alludes to the uncertainties current in connexion with circulation, digestion, generation, and muscular tonicity, and refers to the pioneer work of Borelli, Keil and Jurin in cardiac physiology. He exposes the errors of Descartes regarding digestion and circulation, and heaps ridicule on the casuist Sanchez and the philosopher Maupertuis for their extraordinary views on generation and embryology.

Voltaire's interest in public health was shown not only by his desire to control small-pox by inoculation, and syphilis by a league of nations to combat the disease—a project not realised until the formation of the Union internationale contre le péril vénérien in 1923—but also by his allusion to other epidemic diseases, especially plague and malaria, and his condemnation of the insanitary condition of the Paris hospitals, in which overcrowding and cross infection were rife. He also showed his concern for public health in his references to the abuses connected with the administration of military hospitals, the congested state of the Paris cemeteries and the practice of burial in churches, as well as by his proposal to found maternity hospitals for unmarried women.

---

University and Educational Intelligence.

CAMBRIDGE.—Plans have been prepared for the proposed building which is to house the Departments of Pathology and Animal Pathology. These are now exhibited. It is laid down that the total cost of designing, building, maintaining, and equipping the structure shall not exceed the sum of 115,000*l*., which is being provided by the Rockefeller Trustees (100,000*l*.) and the Development Commissioners (15,000*l*.). The proposed site is in the south-west corner of the area purchased from Downing College for the erection of the science schools.

DURHAM.—The Council of Armstrong College, Newcastle-on-Tyne, conferred the honorary title of reader in Genetic on Dr. J. W. H. Harrison, lecturer in zoology.

Mr. J. F. Duff has been appointed lecturer in education in succession to Mr. W. O. Brigstocke, who has received a similar appointment in the University of Liverpool. Dr. T. Iredale has been appointed lecturer in chemistry, in succession to Dr. V. G. Jolly, who has gone to an industrial post. Dr. Iredale is an Australian, and a graduate of the Universities of Sydney and London. Since 1921, when he first came to England, he has been carrying out research and demonstrating in chemistry in University College, London.

EDINBURGH.—Intimation has been received that His Majesty in Council has approved of Ordinance No. 142, Edinburgh No. 47 (Foundation of the Abercromby chair of archæology).

At a meeting on January 25, the Court agreed to take steps to commemorate in a suitable manner the two-hundredth anniversary of the institution of the Faculty of Medicine of the University, which will occur in the course of the present year.

Dr. and Mrs. Inglis Clark have presented to the Department of Chemistry a valuable quartz spectrograph and appurtenances in memory of their son Charles Inglis Clark, B.Sc., of the University of Edinburgh, who was killed in the War.

LONDON.—The following doctorates have been conferred: *D.Sc.* (*Botany*), on Miss V. M. Grubb (Bedford and Westfield Colleges) for a thesis entitled "The Spermatia of the Florideæ"; *D.Sc.* (Chemistry) on Mr. E. de B. Barnett (University College) for a thesis entitled "Action of Nitrogen Dioxide on Anthracene Derivatives and the Bearing on the Mechanism of Nuclear Substitution"; *D.Sc.* (*Chemistry*), on Mr. H. Phillips (Battersea Polytechnic) for a thesis entitled "The Optical Properties of *n*-Alkyl *p*-Toluenesulphinates"; *D.Sc.* (*Physics*), on Mr. E. P. Metcalfe (University College) for a thesis entitled "(1) On the Selective Absorption of Light by Luminous Gases and certain Consequences resulting therefrom, and (2) On Ionisation in various Gases"; *D.Sc.* (*Psychology*), on Mr. E. H. Magson (University College) for a thesis entitled "How we Judge Intelligence"; *D.Sc.* (*Cytology*), on Mr. R. J. Ludford for a thesis entitled "Studies in Normal and Pathological Cytology," and other papers.

Applications are invited for the Graham scholarship in pathology, value 300*l*. per year and tenable for two years. The latest date for the receipt of applications is February 28. Particulars can be obtained from the Academic Registrar, South Kensington, S.W.7.

MANCHESTER.—On January 20 Mr. W. H. Moberly, the Vice-Chancellor elect, was entertained at dinner by the teaching staff. More than a hundred members from all Faculties attended the dinner, which was held in the Refectory and was organised by the Association of University Teachers. The president, Prof. W. M. Calder, welcomed Mr. Moberly in a happy and informal speech, and the Vice-Chancellor elect in reply spoke of his pleasure at the reception he had received.

This function brought home to members of the University the fact that in a few short months Sir Henry Miers will be leaving, and the Faculty of Science will see his departure with great regret. The Science Departments are grateful to him as professor of crystallography for the active and invaluable department which he created. He has stimulated great interest in his subject, and graduate students have attended his lectures and laboratory with enthusiasm. The Departments of Physics, Chemistry, and Metallurgy owe much to his work, and it is hoped that it will be found possible to continue the department in some form.

Losses from death have been unusually heavy. Mr. James Grant, Dr. Edmund Knecht and Prof. William Myers of the Faculty of Technology, and Mr. C. B. Dewhurst, Clifton lecturer in engineering, all passed away last term, to the great sorrow of the University.

Dr. Henry Stephen, lecturer in chemistry, is leaving to take up the post of professor of organic chemistry at the University of the Witwatersrand, Johannesburg. Dr. G. N. Burkhardt has been appointed lecturer in chemistry.

Prof. F. E. Weiss, Harrison professor of botany in the University, has been elected an honorary member of the Botanical Society of Geneva.

APPLICATIONS are invited by the Battersea Polytechnic for Tate and Morgan scholarships in engineering, science, domestic science, hygiene, and art for the session 1926–27. The scholarships vary in value from 20*l*. to 30*l*. per annum with free tuition, and are tenable for two or three years. The latest day of entry is April 17 next. Full particulars are obtainable from the Principal.

AT the present time seventeen Ramsay Memorial Fellowships in chemical science are being held in the universities and colleges of the United Kingdom. The list of awards for the present session, with the institution selected by the fellow for his research, is as follows: *British Fellowships*, Mr. George A. Elliott (University College, London), Dr. H. Raymond Ing (Oxford), Dr. S. W. Saunders (University College, London); *Glasgow Fellowships*, Mr. James D. Fulton (since resigned), Mr. T. Corlett Mitchell (Cambridge); *Canadian Fellowship*, Dr. Donald McKay Morrison (Cambridge); *Danish Fellowship*, Mr. Kai J. Pedersen (Bristol); *Dutch Fellowship*, Mr. W. G. Burgers (Royal Institution, London); *French Fellowship*, M. Marcel Mathieu (Royal Institution, London); *Greek Fellowship*, Dr. N. Ekonomopoulos (University College, London); *Italian Fellowship*, Dr. Paolo Misciattelli (Oxford); *Japanese Fellowship*, Dr. Seisi Takagi (University College, London); *Norwegian Fellowship*, Mr. Leif Lindemann, 1924–25 (Sheffield), Mr. Karl Sandved (Imperial College of Science and Technology, London); *Spanish Fellowship*, Senor Fernando Calvet (Oxford); *Swedish Fellowship*, Mr. Erik Rudberg, 1924–25 (King's College, London), Mr. Gunnar Hagg (commencement of work deferred until October 1926); *Swiss Fellowship* (vacant during 1925–26). The total value of the annual amount of the fellowships that is awarded is approximately 4600*l*., of which about 3100*l*. is provided by grants from dominion and foreign sources.

Contemporary Birthdays.

February 1, 1843. Sir John Isaac Thornycroft, F.R.S.
February 5, 1866. Sir Arthur Keith, F.R.S.
February 6, 1860. Sir Archibald Denny, Bart., M.Inst.C.E.
February 6, 1835. Rev. Thomas R. R. Stebbing, F.R.S.
February 6, 1852. Dr. Conwy Lloyd Morgan, F.R.S.
February 7, 1877. Prof. Godfrey H. Hardy, F.R.S.
February 7, 1840. General Sir Charles Warren, G.C.M.G., F.R.S.
February 8, 1868. Lord Rothschild, F.R.S.
February 8, 1872. Sir Max Muspratt, Bart., M.Inst.C.E.
February 9, 1860. Sir Hugh Reid, Bart, M.Inst.C.E.
February 9, 1871. Prof. Edward C. C. Baly, C.B.E., F.R.S.

Sir John I. Thornycroft, naval architect and engineer, son of Thomas and Mary Thornycroft, both of whom were sculptors, was born at Rome. He was educated at a private school and at the University of Glasgow, coming there under the guidance of Sir William Thomson (Lord Kelvin) and Prof. Rankine. Setting up in business he founded the world-known firm established at Chiswick. Early in his career he designed and built the steam launch *Nautilus*, which proved a complete success. The *Lightning*, the first torpedo boat for the British Navy, was built at Chiswick; it was a pioneer in the design and construction of high-speed craft. Sir John also founded the extensive motor works located at Basingstoke. Here large numbers of motor lorries were constructed for war service, as well as high-speed motor boats.

Sir Arthur Keith, Hunterian professor in the Royal College of Surgeons, was born at Old Machar, Aberdeen. He was educated at Aberdeen, University College, London, and Leipzig. Author of many illuminating and critical contributions to anthropology, he was president of the Royal Anthropological Institute, 1912–14. A lecturer of distinction, Sir Arthur gave a noteworthy discourse before the Royal Society of Medicine in November last, on "The Nature of Man's Structural Imperfections."

Sir Archibald Denny, shipbuilder and marine engineer, of the firm of Messrs. William Denny, Bros., Ltd., Dumbarton, was educated, in the first instance at Dumbarton Academy, afterwards in Switzerland, later entering the Royal Naval College, Greenwich. It may be recalled that in 1877 the British Admiralty sanctioned the admission of one young constructive officer of the Imperial Japanese Navy as a student of naval architecture for two years at the Greenwich College. In 1879 a student of marine engineering was similarly sanctioned. Denny was at the College in 1879 with the first of these students—one Miyabara, who afterwards became an Admiral.

Rev. Thomas R. R. Stebbing, the distinguished zoologist, who celebrates his ninety-first birthday this week, and to whom we proffer our heartiest congratulations, is a Londoner, the fourth son of the Rev. Dr Henry Stebbing, F.R.S., who was acting editor of the *Athenæum* for many years after its foundation in 1828. Thomas Stebbing was educated at King's College School, London, and the University of Oxford. He was a tutor of Worcester College, Oxford, 1865–67, becoming an honorary fellow in 1908. Mr. Stebbing's zoological work has been concerned principally with the Crustacea. He carried to completion a monumental report upon the Amphipoda of the *Challenger* Expedition.

Dr. Lloyd Morgan, emeritus professor of psychology in the University of Bristol, was born in London. Educated at the Royal Grammar School, Guildford, he passed into the Royal College of Science, London. For a number of years he was a science lecturer in an institution in South Africa, returning in 1884 to take up the professorship of zoology and geology in University College, Bristol. Many interesting studies in biology and psychology have proceeded from his facile pen.

Prof. G. H. Hardy is Savilian professor of geometry in the University of Oxford (since 1919) Educated at Winchester, he graduated at Trinity College, Cambridge. He was Cayley Lecturer in the University, 1914–19. Prof. Hardy's recently delivered address as retiring president of the Mathematical Association, with its plea for the abolition of the Mathematical Tripos, has attracted considerable attention. He is a Royal medallist of the Royal Society.

General Sir Charles Warren celebrates his eighty-sixth birthday on Sunday, and we tender our very hearty congratulations. Educated at Cheltenham College, he passed into Sandhurst and Woolwich, entering the Royal Engineers in 1857. From 1867 to 1870 he conducted a series of excavations in Palestine, chiefly round the walls of the enclosure of the Temple of Jerusalem. The results of these early archæological studies were detailed in "Underground Jerusalem" (1876); "The Temple of the Tomb" (1880); and, in conjunction with Capt. Conder, "Jerusalem" (1884). Special Commissioner to settle the boundary of the Orange Free State (1876), he was deputed, in the following year, to arrange the land question which affected West Griqualand. Returning to England in 1880 he became instructor of surveying at Chatham. Sir Charles Warren's active military services are, of course, well known. They refer to Zululand, Bechuanaland, and Suakim.

Lord Rothschild has been for many years a trustee of the British Museum. Born in London, he was educated at Bonn and Magdalene College, Cambridge. Author of numerous works in zoology, Lord Rothschild has brought together large and valuable collections, which receive ample display and elucidation in his beautiful museum at Tring.

Sir Max Muspratt is well known in fields of industrial chemistry. Born at Liverpool, he was educated at Hemel Hempstead, Clifton College, and abroad. He entered the works of the United Alkali Co. in 1895, of which combine he has been successively director and chairman. Vice-president of the Federation of British Industries, he is chairman of the Association of British Chemical Manufacturers. Sir Max was Lord Mayor of Liverpool in 1917.

Sir Hugh Reid was born at Manchester. He was educated at the City High School, and graduated at the University of Glasgow. Managing Director of the North British Locomotive Co., Ltd., he is joint inventor of the Reid-Ramsay steam turbine electric locomotive. During the War he was a member of the Glasgow and West of Scotland Munitions Committee of Management. In 1917 he received the freedom of the City of Glasgow.

Prof. Edward C. C. Baly was educated at Templegrove School, Aldenham, and University College, London. From 1908 until 1910, he was assistant professor of chemistry and lecturer in spectroscopy at University College, leaving to become Grant professor of inorganic chemistry in the University of Liverpool.

Societies and Academies.

LONDON.

Royal Society, January 28.—A. C. **Seward**: The Cretaceous plant-bearing rocks of Western Greenland. The paper deals briefly with the geology of the localities visited, and, more fully, with the plants collected on the coasts of the Nûgssuak Peninsula and on the south-east coast of Disko Island. The fossils obtained include many species previously described by Heer. The Cretaceous plants are regarded as a single flora; Heer's threefold division (Kome, Atane, and Patoot series) is not accepted. Several species of ferns and gymnosperms, generally characteristic of the oldest Cretaceous floras and closely allied to Jurassic types, are found associated with representatives of Angiosperms that are strikingly modern. The Greenland Cretaceous flora seems to be Wealden-Cenomanian in age. It is considered that several deciduous dicotyledons were evolved in Arctic regions, where, in Cretaceous days as now, a short summer with continuous sunshine alternated with a long period of semi-darkness. From their Arctic home the flowering plants spread to the south.—W. L. **Balls** and H. A. **Hancock**: Measurements of the reversing spiral in cotton hairs. The spirals in the cell wall of cotton hairs may be dexter or sinister, and their reversals are apparently predetermined during growth in length. Genetic and ordinary environmental influences do not affect the statistical peculiarities of the reversals. The final adult length of the hair and the time taken in reaching that length do affect the reversal distribution. Nearly all the seed hairs of Gossypium begin to grow on a sinistral spiral. The angle of the helix varies around two modal values, but local variations are quite unaffected by inversion from dexter to sinister.—R. H. **Burne**: A contribution to the anatomy of the ductless glands and the lymphatic system of the angler fish (*Lophius Piscatorius*). The thymus body lies free beneath the mucous membrane of the pharynx, connected with the branchial cavity by a tube. This tube is not a duct, but more nearly resembles the crypts characteristic of the mammalian tonsil. The thyroid body is occupied by a large lymph sinus, into which lymph passes through valved openings from ventral and branchial lymphatics, and from which it is conveyed to the heart by the inferior jugular. Distributed to the mucous membrane of mouth and pharynx, and to the skin of the forepart of the body, is a system of "fine" vessels, similar in structure to small arteries. These vessels are not part of the blood vascular system, but connect by their terminal branches with the ordinary lymphatics. They are probably an afferent system of lymphatics.—I. **Gordon**: The development of the calcareous test of *Echinus miliaris*. All elements of the permanent skeleton which are laid down in the larva are traced back to a single spherical granule. This granule, with two exceptions, becomes a triradiate spicule even in the formation of a tetraradiate spine. The exceptions are in the development of (*a*) the base of a typical echinoid spine where it becomes hexagonal (a modification of the triradiate symmetry), and (*b*) the component parts of a tooth. The development of the tetraradiate spine, the simple and the compound tube-feet discs, and the blade of a pedicellaria is new. The large buccal plates arise interradially, and there are two sets of buccal tube-feet—(*a*) five primary ones with simple discs; (*b*) five secondary ones with compound discs, which are at first ordinary ambulatory tube-feet.—F. G. **Gregory** and L. **Batten**. A critical statistical study of experimental data on the effect of minute electric currents on the growth rate of the coleoptile of barley. A statistical analysis has been made of the data on which results described by Blackman, Legg, and Gregory for the effect of electrification on the growth of the coleoptiles of barley are based. Corrected data for the controls and four electrified sets show *positive* results, and, taken together, provide markedly significant evidence of the physiological effect of the discharge.—H. M. **Fox**: Chlorocruorin: a pigment allied to hæmoglobin. Chlorocruorin is a polychæte blood-pigment. It is red in concentrated, green in dilute, solution. It exists in oxidised and reduced forms, having spectra analogous to oxy- and reduced hæmoglobin. The oxygen affinity is less than that of hæmoglobin. Specific chlorocruorins differ in oxygen affinities; some are unsaturated at atmospheric pressure. Whereas hæmoglobin and a number of related pigments all contain the same hæmatin nucleus, chlorocruorin has a different hæmatin.

Geological Society, January 6.—W. N. **Edwards**: Fossil plants from the Nubian sandstone of Eastern Darfur. The plant-remains described were found by Mr. G. V. Colchester at Jebel Dirra, 75 kilometres east of El Fasher, in Darfur. They occur in highly silicified quartzitic sandstone, belonging to the Nubian Sandstone, and are the first fossils to be found in that formation in Darfur. The species identified, which probably grew in dune conditions, are *Weichselia reticulata* (Stokes and Webb), *Frenelopsis hoheneggeri* (Ettingshausen), *Dadoxylon ægyptiacum* Unger, and indeterminable fern-fragments. The beds in which they occur are thus assigned to the Lower Cretaceous, or possibly to the base of the Upper Cretaceous.—Vincent G. **Glenday** and John **Parkinson**: The geology of the Suk Hills (Kenya Colony). The Suk Hills lie in the northern part of Kenya Colony, midway between Mount Elgon and the southern half of Lake Rudolf. Sekerr, their highest point, reaches an elevation of nearly 11,000 feet. With insignificant exceptions, the rocks are of Eozoic age, and fall into two groups: a series of completely metamorphosed sediments, probably including ashes, and microcline-orthogneisses. The former group so closely resembles the Turoka series from the border of Tanganyika Territory that they cannot be separated, the whole being contemporaneous in general terms. The second group seems to be intrusive into the first.

PARIS.

Academy of Sciences, December 7.—A. **Lacroix** and Const. A. **Kténas**: The modern lavas of Fouqué Kameni (Santorin). A comparison of the complete analyses of lavas of different dates (1925, 1869, 1866, 1846) shows that the composition has remained almost unchanged.—André **Blondel**: The mechanics of the resonance of torsion of crank shafts.—M. Kamerlingh Onnes was elected a foreign associate in succession to the late Sir Archibald Geikie, and R. A. Millikan was elected correspondent for the section of physics in succession to the late Sir James Dewar.—— de **Séguier**: The divisors of the finite direct Abelian products.—— **Fatou**: A property of certain multiform analytical functions.—Armand de **Gramont**: A precision inverter permitting no articulated system.—R. **Chambaud**: The theory of thick circular arches.—D. **Riabouchinsky**: Some cases of irrotational movements in three dimensions.—Thomas Martin **Lowry** and Bawa Kartar **Singh**: The rotatory dispersion of nicotine. The results are given for three specimens of nicotine for 27 wave-lengths. The dispersion of nicotine was found to be simple.—Jean **Barbaudy**: The dehydration of aqueous alcohol by fractional distillation in the presence of benzene.—A. **Boutaric** and Mme. Y. **Manière**: The influence of the hydrogen ion concentration on the velocity of flocculation of some negative colloids.—P. **Vaillant**: The influence of an electrostatic charge on the superficial conductivity of a plate of rock salt.—P. **Lebeau** and A. **Damiens**: An easy method for the preparation of fluorine. As electrolyte the compound $KF \cdot 3HF$, melting at 56° C., is used. This is placed in a copper or nickel vessel, forming the negative electrode, the positive electrode being a nickel rod 8 mm. in diameter.—Marcel **Godchot** and Pierre **Bedos**: Monochlor-*o*-methylcyclohexanone.—I. **Pouget** and D. **Chouchak**: The radioactivity of the mineral waters of Hammam Meskoutine (Algeria).—N. A. **Critikos**: The seismic phenomena produced before and after the eruption of the volcano of Santorin.—M. **Bridel** and C. **Charaux**: The ferment extracted from the seeds of various species of Rhamnus or rhamnodiastase. Details are given for preparing this ferment from the seeds of *Rhamnus utilis*. It is of interest in that it produces a partial hydrolysis of glucosides, some of the glucoses remaining combined in the form of complex glucides.—Mme. H. **Gauthier-Lièvre**: Some observations on the algæ of Algeria in their relations with the *p*H.—L. **Plantefol**: The forms of growth of *Hypnum triquetrum*.—Raymond **Jacquot** and André **Mayer**: The equilibrium of the cellular constituents and the intensity of the oxidations of the cell. Imbibition and oxidations. The case of seeds.—René **Hazard** and L. J. **Mercier**: The action of the base tropine (tropanol) on the circulation.—P. **Reiss**: The development of the interior *p*H of the egg of the sea-urchin during fecundation and division.—Jules **Wolff** and Lucien **Grandchamp**: Some observations on the oxidisability of the iron contained in wine. The ferrous salts normally present in wine may be rapidly transformed into ferric salts under the influence of an oxydase, thus causing the phenomenon of *casse*.—L. C. **Maillard** and H. **Wunschendorff**: The formation of complexes between proteins and the hydrates of trivalent metals. The method of removing albumen by alums.—L. **Fournier** and P. **Mollaret**: The double hyposulphite of gold and sodium in the treatment of syphilis. The antisyphilitic action of this double salt is fairly energetic in large doses, but the general reactions and frequent skin troubles produced by the treatment present a serious obstacle to the use of this product in the treatment of human syphilis.—Stefan **Jellinek**: Death by electricity, practical results resulting from electropathological studies.

December 21.—L. **Lecornu**: Elastic transmissions. Reply to some criticisms by A. Blondel.—Maurice **Hamy**: The photography of stars in full daylight. An account of some results obtained by a method described in a previous communication. Photographs were taken at varying levels up to a maximum of 3274 metres. At this height, about midday, the extreme limit of photographic impression visible on the negatives, at 90° from the sun, was about the 6·5 magnitude.—A. **Desgrez** and J. **Meunier**: The mineral elements associated with oxyhæmoglobin from the blood of the horse. The metals were detected and roughly determined by the spectrograph. On the product from the first crystallisation, the hæmoglobin contains potassium, sodium, calcium, lithium, and minute traces of manganese. The second crystallisation reduces the marked preponderance of potassium without sensible variation of the calcium.—Félix **Mesnil**: The sensibility of trypanosomes of human origin to normal human serum.—Maurice de **Broglie** and Jean **Thibaud**: The total reflection and variation of the refractive index of the X-rays in the neighbourhood of an absorption discontinuity of the mirror. The measured values for the refractive index agreed within the limits of the experimental error with those calculated by the theory of Drude from the dispersion of electromagnetic waves. Thus the optical properties of the X-rays are identical with those of ordinary light and follow the same laws. This supports the undulatory character of the X-radiations, whilst their photo-electric phenomena bring out their corpuscular or quantic aspect.—Amé **Pictet** and Alfred **Georg**: New syntheses of isomaltose and gentiobose. Lævoglucosane is readily converted into dilævoglucosane, and the latter, by regulated hydrolysis with hydrochloric acid, gives a mixture of glucose and isomaltose. In the preparation of isomaltose by the condensation of glucose according to Fischer's method, there is formed a small quantity of gentiobiose.—E. **Mathias**: Contribution to the study of fulminating material: thermic heterogeneities. Discussion of the nature of ball lightning.—C. **Sauvageau**: The *bromuques* of Antithamnion. In a recent communication the author has indicated the presence of free bromine in the colourless refractive cells of *Antithamnionella sarniensis*, and has proposed the name of *bromuques* for these organs. Five species of Antithamnion, dried and pressed, have also been found to give the bromine reaction. Hence the *Blasenzellen* or gland-cells of Antithamnion act as organs for accumulating bromine.—René **Garnier**: A new method for solving the problem of Riemann.—Paul **Lévy**: The ratio between an integral series and its greatest term.—J. **Renaux**: A method of special perturbations.—Jean **Chazy**: The advance of the perihelion of Mercury.—Th. **Vautier**: The propagation of air waves produced by sparks or by percussion caps.—Mlle. Paule **Collet**: The constant paramagnetism of solutions: The atomic coefficient of magnetisation of chromium, whether deduced by the ascension method from a solution of potassium bichromate or from the attraction method using the solid salt, is the same.—Hippolyte **Copaux** and André **Copaux**: A method of estimating coloured gases, based on the use of the photo-electric cell, and its application to the case of nitrous vapours. The light, after passing through a column of the gas, falls on a photo-electric cell, and the deflexions of the galvanometer are plotted against the percentage of nitrogen peroxide. With gases containing between 0·2 and 0·7 per cent. of nitrogen peroxide, the latter can be determined with an accuracy of 0·02 per cent.—René **Dubrisay**: The application of capillary measurements to the study of mixtures of fatty acids. Measurement of the surface tension at the surface of separation of benzene solutions of mixtures of fatty acids and their alkaline aqueous solutions is shown to be a useful means of identifying certain acids and their mixtures.—A. **Kling** and A. **Lassieur**: The hydrogen exponent of water. In view of the fact that recent values for the *p*H of water range from 5·8 to 7·0, the authors have redetermined this constant with many precautions (distillations in platinum, no access of air containing carbon dioxide, etc.), finding for pure water *p*H = 5·8. This deviation from neutrality (*p*H = 7·07) may be attributed to the fact that water has a real acidity, or it may be that the current methods of measuring *p*H are faulty.—J. **Cournot** and K. **Sasagawa**: The variation with temperature of the resistance of ordinary mild and hard steels to shock by traction.—C. **Matignon** and J. **Cathala**: The action of phosgene upon glucina. The preparation of beryllium chloride The use of sulphur chloride for the preparation of anhydrous beryllium chloride, on account of the difficulty of separating the sulphur chloride, leads to an impure product. Carbonyl chloride, now a commercial product, gives good yields of anhydrous beryllium chloride, when passed over beryllium oxide heated to 1000° C. in quartz vessels.—**A. Raynaud**: The bromination of zinc in the presence of various organic solvents.—**A. Cornillot**: The constitution of the chloro-derivatives of the phthalonic series.—**Jacques Bourcart** and **M. E. Denaeyer**: The lithological characters of the lavas of Ahaggar, Central Sahara (Jacques Bourcart expedition, 1922–1923).—**R. Furon**: Geological observations on the Kabul valley (Afghanistan).—**Ch. Maurain** and **L. Eblé**: The propagation of seismic waves in limestone.—**Jean Lecarme**: The ultra-violet radiations of the sun at great altitudes. Using a method of measuring the intensity of the ultra-violet radiations depending on the decomposition of oxalic acid in the presence of uranyl sulphate as a catalyst, measurements have been carried out at various altitudes, the highest being at the Mont Blanc Observatory (4350 metres). It was noted during these experiments that whilst the solar radiation produced a rapid decomposition of the oxalic acid, the effects due to the light of the mercury arc were scarcely sensible. From this it would appear that the solar ultra-violet energy is greater than that of the ordinary mercury arc, although the biological effects are less intense.—**O. Munerati**: Is there an after-ripening in recently plucked cereals?—**Ch. Killian**: Observations on the postembryonic development of *Drosera rotundifolia*.—Mlle. **Panca Eftimiou**: On *Exoascus deformans*.—**Lucien Daniel**: Heredity in *Helianthus tuberosus Dangeardi*.—**Em. André**. Contribution to the study of the oils of the chaulmoogra group. The oils of seven different Flacourtiaceæ, each regarded in the country of origin as possessing curative properties against leprosy, have been extracted and their chemical and physical constants determined. These possess one character in common, the deviation to the right of the plane of polarised light.—**Marcel Baudouin**: Radiographs for the diagnosis of the nature of the human work executed on the teeth in ethnography.—**R. Bonnet**: The influence of variations of external temperature on the magnitude of the specific dynamic action in the Poikilotherms.—**André Mayer** and **L. Plantefol**: The influence of the electrolytes of the medium on the gaseous exchanges of the mosses.—**E. Fauré-Fremiet** and **Robert Wallich**: A physical factor of cellular movement during the cultures of tissues *in vitro*.—**A. Dorier**: The faculty of encystment in water of the larva of *Gordius aquaticus*.—**L. Rapkine** and **M. Prenant**: The reaction of the blastocœlian liquid in the pluteus of the sea urchin in the first phase of development.—**Lucien Cavel**: The nitrogen losses in the purification of sewage by the method of activated sludge.—**G. Mouriquand** and **M. Bernheim**: New researches on the relations between age and the appearance of troubles of avitaminosis C.

Official Publications Received.

Wisconsin Geological and Natural History Survey. Bulletin No. 65. Educational Series No. 8: The Geography of Southwestern Wisconsin, By W. O. Blanchard. Pp. viii+117. Bulletin No. 66, Economic Series No. 22: Limestones and Marls of Wisconsin By Edward Steidtmann; with a Chapter on the Economic Possibilities of Manufacturing Cement in Wisconsin, by W. O. Hotchkiss and H. F. Bean. Pp. x+206+6 plates. Bulletin No. 67, Educational Series No 9: A Brief Outline of the Geology, Physical Geography, Geography and Industries of Wisconsin. By W. O. Hotchkiss and H. F. Bean. Pp. iv+60. (Madison, Wis.)

Notas geofisicas y meteorologicas publicadas por el Observatorio Nacional de San Bartolomé de Bogotá. Numero 2: Los Huracanes de las Antillas. Por Rev. Simon Sarasola. Pp. vii + 172. (Bogotá, Colombia)

Memoirs of the Department of Agriculture in India. Chemical Series, Vol. 8, No. 5: Nitrogen Recuperation in the Soils of the Bombay Deccan, Part I. By D. L. Sahasrabuddhe and J. A. Daji. Pp. 53-68. (Calcutta: Government of India Central Publication Branch.) 4 annas; 5d.

Journal of the Royal Society of Western Australia. Vol. 11, 1924–1925. Pp. xii+163+iii. (Perth.) 21s.

Diary of Societies.

SATURDAY, February 6.

Royal Society of Medicine (Otology Section), at 10.30 A.M.—Dr. D. McKenzie: Report on a Case of Temporo-sphenoidal Abscess.—F. W. Watkyn-Thomas: Report on a Case of Necrosis of the Petrous Bone.

Association of Women Science Teachers (Annual General Meeting) (at St Paul's Girls' School), at 10.30 A.M.—Educational Films, chiefly Scientific, shown by the Visual Education Society.—At 2.30.—Miss Coward: The Teaching of Hygiene in Schools; Short Papers on the same subject.

Society of Chemical Industry (South Wales Section) (jointly with Institute of Chemistry and Wales and Monmouthshire Junior Gas Association) (at University College, Singleton Park, Swansea), at 2.30.—C. A. Seyler: The Microscopy of Coal.

Royal Institution of Great Britain, at 3.—Sir Walford Davies: The Triad and the Perfect Fourth (1).

Gilbert White Fellowship (at 6 Queen Square, W.C.1), at 3.—Miss L. E. Cheesman: Insect Collecting in the Society Islands.

Institute of British Foundrymen (Lancashire Branch) (at Grand Hotel, Manchester), at 4.—J. G. Robinson: A Day in the Foundry (Lecture).

Hull Association of Engineers (at Technical College, Hull), at 7.15.—Fuel Oil and its Applications (Lecture).

MONDAY, February 8.

Royal Irish Academy, at 4.15.

Biochemical Society (at Lister Institute), at 4.30.—H. Chick: Sources of Error in the Biological Method of Investigating Fat-soluble Vitamins.—P. Hirsch: The Serum Diagnosis of Malignant Growths with the Interferometer.—P. C Raiment: The Oxidation of Uric Acid with Hydrogen Peroxide.—L. S. Maclean and D. Hoffert: The Synthesis of Fat by the Living Organism.—N. Wright: The Action of Hypochlorites on Amino Acids and Proteins.—R. H. Marriott: The Action of Sodium Sulphide on Hair.

Royal Society of Edinburgh, at 4.30.—Prof. H. Briggs: The Wheatstone Bridge as the Means of Measuring Linear and Angular Dimensions at a Distance, and its Application to Borehole Surveying.—Prof. E. T. Whittaker: On the Adjustment of Sir J. J. Thomson's Theory of Light to the Classical Electro-magnetic Theory.

Victoria Institute (at Central Buildings, Westminster), at 4.30.—Prof. F. F. Roget: A Philosophic Exponent of Latin Culture, Alexandre Vinet: Protestant Divine and Literary Critic (1797–1847).

Royal Society of Medicine (War Section) (at Central Medical Board, Royal Air Force, 3 and 4 Clement's Inn), at 5.—Demonstration: The Medical Examination of Candidates for Aviation, with Particular Reference to the Physiological and Ophthalmological Tests Employed.

Royal College of Surgeons of England, at 5.—Prof. A. Tudor Edwards: The Surgical Treatment of Phthisis and Bronchiectasis.

British Institute of Philosophical Studies (at Bedford College for Women), at 5.30.—Prof. J. Johnstone: Failure of Mechanistic Conceptions of Life: Neo-vitalism.

Institution of Structural Engineers (Students' Meeting), at 6.—H. K. Dyson and others: Discussion.

Institution of Automobile Engineers (Birmingham Centre) (at Chamber of Commerce, Birmingham), at 7.—T. D. Carpenter: Modern Chassis Frame Design and Body Mounting.

Institution of Electrical Engineers (Informal Meeting), at 7.—R. J. Mitchell and others: Discussion on Modern Applications of Ball and Roller Bearings.

Institution of Electrical Engineers (North-Eastern Centre) (at Armstrong College, Newcastle-upon-Tyne), at 7.—Prof. S. P. Smith: An All-Electric House.

Institution of Mechanical Engineers (Graduates' Section), at 7.—H. C. Peters: Submerged Combustion and Submerged Flame Burners.

Surveyors' Institution, at 8.—E. M. Konstam: The Rating and Valuation Act, 1925.

Royal Geographical Society (at Æolian Hall), at 8.30.

Medical Society of London, at 8.30.—H. W. Carson, Dr. A. F. Hurst, and Dr. T. W. Eden: Discussion on Right Iliac Fossa Pain.

TUESDAY, FEBRUARY 9.

Manchester Geological and Mining Society, at 4.

Royal Institution of Great Britain, at 5.15.—Dr. E. K. Rideal: Surface Action (2).

Institution of Petroleum Technologists (at Royal Society of Arts), at 5.30.—Dr. F. Challenger, J. Haslam, R. J. Bramhall, and J. Walkden: The Sulphur Compounds of Kimmeridge Shale Oil.

British Institute of Philosophical Studies (at Bedford College for Women), at 5.30.—Prof. L. J. Russell: Modern Science and the Nature of Matter.

Zoological Society of London, at 5.30.—Secretary: Report on the Additions to the Society's Menagerie during the months of November, December, 1925, and January 1926.—R. I. Pocock: (1) The External Characters of an Adult Female Chinese Pangolin (*Manis pentadactyla*); (2) The External Characters of a Young Female Rodent, *Dinomys branickii*, exhibited in the Society's Gardens.—Dr. R. Broom: On the Mammalian Presphenoid and Mesethmoid Bones.—W. N. F. Woodland: On the Genera and Possible Affinities of the Caryophyllaeidae—a Reply to Drs. O. Fuhrmann and J. G. Baer.—H. G. Institution of Mechanical Engineers (Leeds Branch).—A. P. Hague: The Choice of Steels for Engineering Work.

West of Scotland Iron and Steel Institute (at Royal Technical College, Glasgow).—H. J. Young: Grey Iron Castings for Special Needs.

SATURDAY, FEBRUARY 13.

North of England Institute of Mining and Mechanical Engineers, at 2.30.

Royal Institution of Great Britain, at 3.—Sir Walford Davies: The Third and the Perfect Fourth (2). Their Uses from Hucbald to the Present Day.

British Psychological Society (at Bedford College for Women), at 3.—Dr. M. H. Magson: Judgments of Intelligence based upon Interviews.—R. J. Bartlett: Indications of a Logarithmic Law in Learning.

Scottish Junior Gas Association (at Royal Technical College, Glasgow), at 7.—A. Philip: Municipal Gas Undertakings: Finance and Accounting.

Mining Institute of Scotland (at Edinburgh).

PUBLIC LECTURES.

SATURDAY, FEBRUARY 6.

Horniman Museum (Forest Hill), at 3.30.—W. J. Perry: The Quest for Gold and Pearls in Ancient Times.

MONDAY, FEBRUARY 8.

University of Leeds, at 5.15.—Prof. A. Harden: The Carbohydrate Metabolism of Micro-organisms.

King's College, at 5.30.—Dr. F. A. P. Aveling: The Human Will (4): Modern Views—Theoretical.

TUESDAY, FEBRUARY 9.

King's College, at 5.30.—Miss Hilda D. Oakeley: Philosophy and History (2): Theories of Croce and Gentile.

FRIDAY, FEBRUARY 12.

University College, at 5.—Dr. G. Martin: The Theory of Fine Grinding.

Municipal Technical School, Birmingham, at 7.15.—Dr. J. Newton Friend: Historical Chemistry: Joseph Priestley.

Birkbeck College, at 6.15.—Capt. F. Maccunn: Educational and other Methods of Promoting the Humane Treatment of Animals.

SATURDAY, FEBRUARY 13.

Horniman Museum (Forest Hill), at 3.30.—H. N. Milligan: Sea-Shells and their Makers.

The equipment of this remarkable expedition was superb. In the selection of each instrument, the test applied was that it should be the best for the purpose within the limits of weight and dimensions suitable for human transport. It included a zenith telescope of 615 mm. focal length for latitude observations; for time and azimuth determinations, a telescope with two stands, so as to serve either as a transit instrument or as a 12-in. theodolite; a pendulum apparatus for determining gravity; a chronograph and a number of chronometers, mercurial barometers and hypsometers, sextants with tripod stands and mercury troughs, tacheometers, a level, a base-measuring apparatus, instruments for determining the magnetic elements, besides gas cylinders, pilot balloons, a radio-telegraphic set, photographic apparatus, plates and films.

The accounts are written by the experts who were in charge of the several operations, namely: Capt. A. Alessio, who later became hydrographer of the Italian Navy; Prof. G. Abetti, of Florence; Mr. J. A. Spranger and Lieut. C. Antilli, of the Italian engineers.

The latitude observations (Chap. i.) are very clearly described by Prof. Abetti. Eleven principal latitudes were observed with probable errors varying from ±0″·11 to ±0″·34, the average being ±0″·17. This is a precision which is more commonly associated with major geodetic operations than with the exploration of little-known regions of great natural difficulty; indeed, a very striking feature of this expedition is the contrast between the difficulties of the region and the refinement of the methods employed.

The time determinations (Chap. ii.) were undertaken, first, for the determination of the difference of longitude between the stations of the expedition and Dehra Dun, the headquarters of the Trigonometrical Survey of India, and secondly, for finding the rate of the chronometer used in timing the pendulums in the gravity observations.

As there was no wireless station in India for the emission of controlled time signals, it had been arranged that at certain hours, on certain days during a considerable period, the wireless station at Lahore should emit a series of suitable signals. A comparison of the local time of the reception of these signals at Dehra Dun and at a station of the expedition gives the difference of longitude of the latter from Dehra Dun. In this way the longitudes of eight stations were determined, and at each of them the latitude was also observed. Of these stations, Skardu, Ḳarghil, Lamayura, Leh and Depsang are connected with India by triangulation. At each of these five, therefore, it will be possible to determine the total local deflexion of the plumb line, and these observed values, together with the values calculated by Hayford's method on the isostatic hypothesis, will appear in Vol. 2 of this series and should yield results of the highest interest. The remaining three stations at which the latitude and longitude were determined are Sughet Karol, Yarkand and Kashgar, all in Turkestan. The positions of the last two were tolerably well known, but the fixation of Sughet Karol adds a useful point in a little-known region.

In Chap. iii, on the determination of positions by the methods of nautical astronomy, Capt. Alessio discusses the advantages for both latitude and time determinations of the prismatic astrolabe as compared with a zenith telescope and transit instrument. His decision was in favour of the latter. For use at secondary stations, where portability was of first importance, he declared a distinct preference for a sextant mounted on a tripod stand with mercurial horizon. It would be interesting to know whether he would come to the same decision to-day, fourteen years later, if the same choice lay before him. In such a matter, personal predilection must always be a factor of importance, yet with an observer so versatile and so practised as Capt. Alessio, it is unlikely that predilection was confined to narrow limits, and this fact gives special interest to the discussion and to his decision This chapter also contains an account of the watch kept on the rate of the chronometers and of the determination of various differential longitudes by the transport of some of them. This method was only employed when wireless was not available; indeed, the strong battery of chronometers included in the equipment was intended as a *pis aller*, in case it had been found impossible to arrange for the emission of wireless signals.

Chap. iv. contains a very complete account of the determination of altitude by barometers and hypsometers, also by Capt Alessio. Five mercurial barometers came with the expedition from Genoa, and an additional and particularly good instrument was brought by Prof. Alessandri, who carried it—*in senso assoluto*—all the way from Italy to Leh! Of the six, only the last came safely back to Italy; all the others succumbed sooner or later to the vicissitudes of the journey. The care expended on the treatment and on the comparison of these barometers, and the attention to detail in the deduction of altitude from the data obtained, are worthy of study by any one who contemplates making observations of the kind. Indeed, the whole chapter is more like an account of a careful experiment in physics than that of the operations of a party of explorers.

Results obtained with hypsometers are compared with those deduced from the barometers, and Capt. Alessio arrives at the following conclusions: (*a*) That in determinations of atmospheric pressure with a hypsometer, the accidental error of reading is negligible in comparison with the analogous error in reading a barometer; (*b*) that the correction to a hypsometer is a function of the prevailing low pressure and temperature, and tends to increase positively as the prevailing pressure diminishes and as the prevailing temperature increases; (*c*) that if, but only if, it is possible to ascertain the effects of the above two causes (long-continued low pressure and temperature), then a determination of atmospheric pressure with a fully standardised hypsometer is of the same order of accuracy as a determination with a mercurial barometer of the best quality and observed under the most favourable conditions. Great stress is laid on the need for study of thermometers when subjected to such conditions, and it is suggested that the Monte Rosa Observatory might undertake such an investigation.

The triangulation which forms the framework for the map of the area surveyed is dealt with by Mr. J. A. Spranger in Chap v After the establishment of the base camp on the Depsang Plateau, the weather was at first so bad that it was found impossible to make a satisfactory connexion with known peaks, and it was determined to measure a base and start an independent triangulation resting on an astronomically observed latitude and azimuth. However, a week later the weather cleared, and it was then possible to observe peaks in all directions, including several fixed by the Indian triangulation; among these were K^2 and one of the Teram Kangri peaks The chart of the triangulation shows that the system divides into two parts, the dividing line running east and west through the Karakoram Pass, and that the connexion between the two parts is weak. Fortunately, it was found possible to fix the ultimate station towards the north by means of rays to well-fixed points, namely, the Gasherbrum peaks and another (12/52E) which had already proved useful in the southern portion This gives a valuable check, and we may feel confident that the positions of the numerous points on which the topography depends are correct enough for their purpose. The work was immensely difficult, and the success achieved reflects great credit on Mr. Spranger and Major Wood, R.E., who jointly carried it out; nor must we omit to mention the names of the two Indian surveyors, Jamna Pershad and Shib Lal, who did the plane-tabling, and of whom Dr. De Filippi speaks in very appreciative terms.

All the stations at which observations were made are fully described in a special chapter, together with the details of the connexion with the Indian triangulation. The descriptions are supplemented by photographs with arrows marking special peaks, and other arrows in the margins which by their intersection indicate the exact position of the astronomical instrument or the gravity apparatus as the case may be. The care bestowed on these details is much to be commended. Trouble has often been caused in the past by the difficulty of identifying points about which some important fact had been laboriously ascertained

The introduction, which we deliberately mention last, is a masterly summary by Dr. De Filippi of the whole campaign. It is illustrated by a map of the whole region, on the scale of 1/2,500,000, showing the routes followed by members of the expedition. Large-scale maps of Rimu Glacier and of the new area surveyed have already been published in the general report.

It must be remembered that the Eastern Karakoram is one of the most barren and inhospitable regions of the world, cut off from civilisation by hundreds of miles of extremely high mountains where passes are few and liable to be closed by snow even in summer, and that there are no roads or bridges—only rough tracks along the valleys, where possible, or with astounding gradients up and down steep slopes where the water is bank high.

The scientific instruments, camp material and personal luggage of the Europeans alone weighed four tons and required sixty horses and twenty porters, quite apart from the necessary supplies (some six and a half tons) of European food. So carefully had the details been thought out, that all this mass of material was so subdivided that in no case was the work of individual groups hampered, though frequently they were separated by two hundred miles or more from the main party. The first seven months from the end of September 1913 had been spent in strenuous work in and around the Upper Indus valley Meanwhile some fifty tons (about 2250 sacks) of food for the porters and fodder for the horses and yaks had to be assembled in the vicinity of Leh ready to be sent forward as early as the condition of the passes into and out of the Shyok valley made it possible. Everything was timed to a nicety; the whole party, with the scientific equipment and all necessary supplies, assembled early in June 1914 a few miles south of the celebrated Karakoram Pass, on the Depsang Plateau (17,590 ft.), which was to be the headquarters of the expedition for nearly three months.

In this introduction, as in the general report, we realise with pleasure how cordial were the relations between the expedition and the several departments of the Government of India with which it had contact, and also what friendly relations subsisted with the Kashmiri officials, with the caravan leaders and the natives generally. But the most striking feature of both accounts is the simplicity and directness of the narrative, together with the modesty and self-effacement of the writer. The funds so liberally subscribed in Italy were obviously used to the best advantage. Each member of the party was selected as being a specialist in his own branch and devoted unremitting efforts to accomplish the utmost possible. It is not surprising that the investigations have yielded such important results, for it is a fine example of successful team work Yet the reader's attention is so persistently directed to the activities of the various groups that he is apt to forget that the success is very largely due to Dr. De Filippi's master mind, and that his genius as organiser made it possible, not only to carry out all the main objects of the expedition, but also to branch out in other directions far beyond the area originally selected for scientific research.

The Kinetic Theory of Heat.

Müller-Pouillets Lehrbuch der Physik. 11 Auflage. Dritter Band, Zweite Halfte: *Kinetische Theorie der Warme.* Von Karl F. Herzfeld. Pp. x+436 (Braunschweig: Friedr Vieweg und Sohn A.-G., 1925.) 21 gold marks.

It is stated in the preface to this treatise on the kinetic theory of heat that there exists, on one hand, a number of adequate works on the kinetic theory of gases, and on the other hand, a number of very complete treatises on statistical mechanics, but that there is no text-book which gives a comprehensive treatment of the various applications of the kinetic theory in a convenient form. This gap Prof. Herzfeld has set out to fill, and he has been so successful that we could wish that his work was available for English students in their own language.

The first chapter contains an elementary treatment of the kinetic theory of gases, and it is at once evident that the author clearly realises the great importance of stating the precise mathematical and physical interpretation of every assumption made and of every equation obtained, a fact which contributes in no small measure to the success of the book. The discussion of the Maxwell distribution of velocities is accompanied by clear descriptions of Bahr's work on carbon dioxide bands, Stern's investigations of molecular velocities, and the work of Cantor, Minnaert, and Wulf. The portion of the chapter devoted to the consideration of the viscosity of gases and allied phenomena contains short sections on the Gaede molecular pump, the Knudsen absolute manometer, and the diffusion pump.

The second chapter deals with general statistical mechanics; the author has again tried as much as possible to emphasise the physical meaning of each statistical formula, and the use of very advanced mathematics is avoided. The treatment of the behaviour of [illegible] apter loses a good deal of its reference value by the omission of any account of the numerous attempts, other than that of Van der Waals, which have been made to obtain a satisfactory equation of state. The author considers them to be practically useless, but, whether that be so or not, they are at least of considerable interest, and, after all, much other scientific work has, in all probability, little further claim on our attention. The English reader must deem it remarkable that in this chapter of forty pages, containing nearly ninety references to original papers, only three of these references are to the work of English and American workers, namely, to the work of Dushman, Rideal, and "McLewis."

The succeeding chapters on solids, the theory of fluids, and the theory of solutions are very extensive, and the sections on sublimation and liquid crystals are of special interest. An excellent treatment of Brownian motion is given in the chapter on the theory of fluctuations, and the developments of the quantum theory, in so far as they affect the kinetic theory, are concisely introduced in Chap. viii. The final chapter deals with the determination of the Loschmidt number and of the absolute dimensions of molecules; it contains a brief account of Rankine's work on this subject, and concludes with a short history of the development of the atomic hypothesis.

The book forms a valuable work of reference, and can be more particularly recommended to those workers who, being conversant with recent English contributions to its subject matter, require ready access to the results of German investigators.

Indian Botany.

The Botany of Bihar and Orissa: an Account of all the known Indigenous Plants of the Province and of the most Important or most commonly Cultivated Exotic Ones. By H. H Haines. (Published under the authority of the Government of Bihar and Orissa.) In 6 Parts. Part 1. Pp. x+199. 8 rupees. Part 2. Pp. 224. 10 rupees. Part 3: *Calycifloræ.* Pp. 225-418. 9 rupees. Part 4: *Gamopetalæ.* Pp. 419-754. 13.8 rupees. Part 5. Pp. 755-1058. 11 rupees. Part 6, including Appendices and Index to Parts 2-6. Pp. 1059-1350. 10.8 rupees. (Calcutta. Thacker, Spink and Co.; London: W. Thacker and Co., 1921–25.)

With the issue recently of Part 1, Mr. H. H. Haines has brought to a conclusion his account of the botany of Bihar and Orissa, and removed thereby another large slice from the area of Peninsular India not yet provided with a flora of its own. The first part was published in 1921, so that the work has been completed in the short space of four years. It must not be thought, however, that it is the product of only forty-eight months of labour, for Mr. Haines had been working on it before he left India, and indeed the contents themselves are full of evidence of the careful preparation of years of research in the field and in herbaria, and of personal acquaintance with the living plants in their natural habitat.

The system of classification adopted closely follows that of Bentham and Hooker with some modifications; *e.g.* the Euphorbiaceæ follow immediately after the Tiliaceæ. This arrangement is not because the author is convinced that it is inherently the best, as indeed will be realised from a study of his discussion on taxonomy and classification, but because, being that followed by most English herbaria, it is the most convenient for English field botanists.

Mr. Haines has taken great pains to give the correct botanical nomenclature according to the International Rules, and to adopt the later developments in raising some of the Bentham and Hooker tribes to the rank of families; *e.g.* with the Urticaceæ. Even when one does not entirely agree with him, his expositions are always illuminating. The keys to the families and genera are Mr. Haines's own and are generally clear and easily applied, and the descriptions are sufficiently detailed to enable any field botanist to make quite certain of his identification. That they are accurate needs no assertion; they are based on intimate and painstaking observation and the study of type specimens. Localities of occurrence and dates of flowering and fruiting are furnished for each species, and also notes on the uses of various parts of the plant.

Part 1 is the most interesting from the general aspect, as it includes, besides a fairly detailed and very interesting account of the area comprised and its topography, geology, and climate, an arresting and lucid dissertation on the general character of the flora, which denotes a most intimate acquaintance with the tract as well as a love for the study of its flora. The chapter on taxonomy and classification is thoughtful and stimulating, and concludes with a conspectus of orders and families in their interrelationship as conceived by the author. The part concludes with a glossary of the botanical terms used and an index for this part—there being a separate index at the end of Part 6 for the other five parts, which are devoted to the descriptive flora itself.

An outline map of the distribution of the rainfall is attached to the chapter on climate, and in a pocket at the end of Part 1 will be found a good topographic map of the Province. The type and paper are excellent, and there can be nothing but praise for this achievement of Mr. Haines, for which all botanists, and particularly those directly interested in the locality, will be grateful.

Our Bookshelf.

Die Tierwelt der Nord- und Ostsee. Herausgegeben von G. Grimpe und E. Wagler. Lieferung 1 (Teil VI. d, VII. a, XI. a). Teil VI. d: Echiuridæ, Sipunculidæ, Priapulidæ, von W. Fischer; Teil VII. a: Enteropneusta, von C. J. van der Horst, Teil XI. a: Pantopoda, von Johannes Meisenheimer. Pp. 55+12+12. (Leipzig: Akademische Verlagsgesellschaft m. b. H., 1925.) 4·80 gold marks.

THE series of which this forms the first section is planned to give an account—systematic, biological, ecological—of the fauna of the North Sea and the Baltic, and is expected to be completed in about 2000 pp. in three years. Each part deals with one group of animals, is separately paged, and bears a number in Roman figures and a letter, so that eventually all the parts with the same Roman figure can be placed together and bound in the sequence indicated by the letters; *e.g.* all the parts on Cœlenterata will be headed "III." followed by one of the letters a-f according to the class or order—the part on Ctenophora will be marked "III. f."

The accounts are intended to be of service to those teachers, students, and amateurs who wish rapidly to refer to the systematic characters and to ascertain the principal facts in the biology of the animals of the area. The descriptions of external and internal characters are necessarily brief, and some previous knowledge is necessary for a proper understanding of the text, but a good third-year student should find little difficulty in using the work.

In Dr. Fischer's part, the Echiuridæ, Sipunculidæ, and Priapulidæ are treated separately. A statement of the characters of the family is followed by a key to the genera. A short diagnosis of each genus and species is given, the localities in the North Sea and the Baltic from which the species has been recorded are mentioned and shown on a map, and the general distribution briefly indicated. In the space of about a couple of pages, a summary is given of the anatomical features which can be made out by the naked eye or with the help of a lens or a binocular dissecting microscope, with references here and there to microscopic structure. Locomotion, food, reproduction, and development are successively considered, and attention is directed to parasites and to those members of the family which commonly serve as food to fishes. Dr. Fischer's work is well up-to-date; it includes, for example, adequate notice of the investigations of Baltzer on Bonellia (1914 and 1924), and appended is a list of works of reference. The illustrations on the whole are good; a better one of the female Bonellia might have been given.

The account of the Enteropneusta follows similar lines. In the part on the Pantopoda a key is given to families only; this part would have been much more useful if keys had been added for the genera and for the fifteen species.

Judging from the portion before us, the series is likely to fulfil its functions very satisfactorily. We cordially wish success to the enterprise, which should result in placing in the hands of those whose work or pleasure leads them to examine the fauna of the North Sea the means for rapidly determining their captures, and for ascertaining the

The Radio Year-Book 1926 (Fourth Year): a Book of Reference for all Interested in Broadcast Receiving. Pp. xiv + 182. (London: Sir Isaac Pitman and Sons, Ltd., 1926.) 1*s.* 6*d.* net.

This book will prove of value to all who listen to broadcasting. Photographs are given of many of the eminent men and of many of the popular artistes who have spoken or performed before the microphone during the past year. So far as British broadcasting is concerned, this year will be a momentous one, as the Government will have to come to a decision regarding the future of the British Broadcasting Company. The book is not a mere record of past achievements; many of the contributions look into the future and make conjectures as to new developments. Mr. Thorne Baker discusses the problem of the radio transmission of visual images. He shows that theoretically it is possible to have a screen in one's home on which, for example, the progress of the yachts at a regatta, possibly hundreds of miles away, could be watched. He points out the difficulties in the way, but says that they have nearly all been overcome by Mr. Baird.

The technical section of the book gives many useful hints on the management of receiving sets and aerials. A chapter has been included on "speaking" films by Mr. Elwell; the reason being that the three-electrode valve has proved of the greatest value in this connexion. Dr. Lee de Forest is rightly given the credit of being the pioneer of perfectly synchronised talking motion pictures, which are called "phonofilms" in America. We learn that the talking motion picture in a commercially perfect form will shortly be introduced into Great Britain. A chapter is also devoted to loud-speaker extensions, and a system of wiring the various rooms of a house so that each room can have its own loud speaker or head-phones if so desired is described. A drawback to the method, however, is that if one is speaking in a room with a loud speaker, a listener on the phones in another room hears most of what is said.

Intermediate Mathematics (Analysis). By T. S. Usherwood and C. J. A. Trimble. Pp. xii + 457 + xxiv. (London: Macmillan and Co., Ltd., 1925.) 7*s.* 6*d.*

The authors of this text-book on mathematics to the intermediate degree standard have already established a reputation by their previous works which is fully maintained in the present. The book is well planned. It commences with simultaneous and quadratic equations and moves easily to the study of simple graphs and their applications to the determination of observational laws and to the approximate solution of equations. Following a chapter on algebra there come two on trigonometry and one on co-ordinate geometry. The three succeeding chapters return to algebra. Chaps. xi. and xii. deal respectively with vectors and trigonometry of the triangle, and the book is completed with two chapters on the calculus up to elementary differential equations.

The book is well supplied with an admirable collection of varied examples. The argument is well developed and evidently based on a critical teaching experience. If a suggestion may be offered, it is that the subject of vectors is too much segregated within its one chapter. There is no reason why it could not be reintroduced in examples of differentiation, integration and differential equations. Applications of the method of least squares might, moreover, with advantage be introduced into the sections treating of maxima and minima and the determination of observational laws.

In Praise of Birds: Pictures of Bird Life. Described and photographed by the Rev. Canon Charles E. Raven. Pp. xiv + 148 + 48 plates. (London: Martin Hopkinson and Co., Ltd., 1925.) 14*s.* net.

Dr. C. E. Raven, Canon of Liverpool, has produced an attractive volume in praise of birds and of bird-watching. The story of his quests shows him to be an ardent bird-lover who takes a proper pleasure in every aspect of bird-life and in every opportunity of studying it on intimate terms. His photographs are evidence of much patient zeal: they are of varying merit, but the best are very good indeed. The author takes us from Cambridge to Surrey, with occasional excursions elsewhere; and finally on a visit to the Dutch coast, to the ornithological wonders of which about half the book is devoted. Incidents both of bird-life itself and of experiences in watching and photography are pleasingly described, and a happy enthusiasm for the subject pervades the whole account.

Physik in graphischen Darstellungen. Von Felix Auerbach. Zweite Auflage. Pp. xii + 257 Tafeln + 29. (Leipzig und Berlin: B. G. Teubner, 1925.) 14 gold marks.

The author of this work must be a real enthusiast for graphical representation. From every branch of mathematics—pure and applied—physics, chemistry, and metallurgy, he has collected together graphs and drawings to illustrate the principal features and the most critical phenomena of these subjects. In many cases the drawings are new, but more frequently they are reproductions of those that appeared in the original memoirs dealing with the particular phenomenon. In all there are 1557 figures in 257 pages, followed by 25 pages of short explanations of each figure, with references. The drawings are well reproduced and combine together to provide a most interesting "picture" book for the scientific worker.

The Configuration of the Saccharides. By Prof. Dr. J. Böeseken. Translated into English from the Dutch by Dr. Samuel Coffey. Part 1: The Configuration of the Monosaccharides. Pp. iii + 71 + iv. Part 2: The Configuration of the Polysaccharides. Pp. ii + 58 + iii. (Leyden: A. W. Sijthoff's Publishing Co., n.d.) n.p.

In these two monographs, the professor of pure and applied organic chemistry in the Technical University of Delft, Holland, has presented a clear and succinct account of the investigations which have led to the most recent views on the molecular configurations of the members of the sugar group. The work is well done and will be valued as a handy and accurate résumé by the research worker, the lecturer, and the student. Although quite intelligible, the translation appears to be too literal, and we fear that much of the phraseology employed would not be passed by the Society for Pure English.

Letters to the Editor.

On One-Eyed Vision.

I CALL "solid" or "three dimensional" vision the faculty of the brain to interpret the flat retinal images so as to give the impression of a three-dimensional space. A person with two healthy eyes views the same object from two slightly different angles, when the muscular effort required to bring the two images into coincidence serves as the guide for estimating the distance. This is the generally accepted explanation, but shortly after I had lost the sight of one eye, a friend expressed doubts of its sufficiency on the ground that if he alternately shut and opened one of his eyes, he noticed very little—if any—difference in the three-dimensional impression. I could understand his scepticism, because previous to my accident I had experimented in the same way with the same result. Since then experience has shown me that there is a very substantial distinction between the permanent and temporary closing of one eye.

Before explaining the inconclusive nature of the described experiment, we may consider what powers the one-eyed person retains to help him in estimating the distance of an object. So long as he is young, he may find sufficient assistance in the focussing effort of the eye, but in old age, when that power is gone, what is left?

Everybody who is in the habit of visiting picture galleries must have occasionally come across a painting which gives an almost compelling illusion of a three-dimensional space. Apart from the imitation of atmospheric effects, it is the correct perspective and the true appreciation of the relative sizes of the objects that give a feeling of solidity, which artists occasionally enhance by wilful exaggeration. A picture has the same appearance whether looked at with one eye or two, and it is the "perspective" vision—as it may be called—on which in old age a person who has lost one of his eyes has to depend.

One-eyed vision is not flat, but it is untrustworthy because the unconscious mental process involved, depending on a knowledge of the dimensions of objects and their relation to the apparent sizes, is liable to be seriously at fault. A few examples derived from experience may illustrate this.

If we are accustomed to a wine glass of a certain size we may fill it with fair safety, but if another glass of similar shape and different size is substituted the result may be disastrous; we have a wrong idea of size in our mind, and this leads to a wrong impression of distance. In our homes we are familiar with most of the objects that surround us, but there are some exceptions. I find flowers in a room difficult to locate when the receptacle in which they are placed happens to be hidden. The flowers then seem to cling to the object with which they are in apparent contact. They may appear in the hair or in the hat of a lady sitting in front; and within the last few days I have seen a man drinking his tea with two fine roses growing out of his bald skull. The same is true of moving objects. A fly passing quickly across my field of vision is almost indistinguishable from a bird flying across the window. If such errors occur when we are fully conscious, they are much more striking at the moment of awakening from sleep. Once, in a somnolent condition, I had the firm impression of seeing in a corner of my study what looked like a tin box perhaps 18 inches long and 6 inches high; but rousing myself I found I was looking at a small tin cigarette box standing on a table beside me.

Most people know how, even with full command of two eyes, their sight may be interpreted in different manners. A rotating cup-anemometer may, for example, look as if the direction of rotation were inverted. Similarly, if a transparent cube be drawn in perspective, all twelve edges showing, we may by an effort of mind get two entirely different impressions of the cube, in which it appears as seen either from above and the right, or from below and the left. Similarly, a cone drawn in outline may appear to be turned inside out by an effort of the will. This shows how much the mind is concerned in the process of solid vision.

If we now return to the experiment described in the opening paragraph, we realise that the two-eyed person looking round a room has a firm impression of the three-dimensional relations of the objects he sees. That impression remains when he shuts one eye, and he is not conscious of any difference. He would have to bandage one eye for some time and go into new surroundings before the test could have any value.

There is another set of interesting and puzzling impressions which lie outside the immediate objects of this communication. It concerns objects in motion. We know all motion to be relative, but nevertheless when a moving train passes a stationary one a passenger in either of them, disregarding relativity, forms a definite and often wrong impression as to whether he is moving or at rest. During the first few months after I had lost one eye, an unconscious swaying of my head always appeared to me as a motion of the surrounding objects, and when these objects were close to my face a most unpleasant sensation of their rapid approach resulted.

I may in conclusion refer to the well-known interpretation of the apparent size of the moon when near the horizon, as showing how much psychological processes affect the interpretation we give to what our eyes perceive.

ARTHUR SCHUSTER.

Yeldall, Twyford,
Berks.

The "Modified Scattered" X-Radiation.

MAY we now supplement what we have already told regarding the scattering of X-rays by stating that we now know quite definitely that even after the *J*-transformation has taken place in a scattered X-radiation and this has become a "modified scattered" radiation when its absorbability is measured in certain substances, it has, even after passing through those substances, precisely the same absorbability as the primary when measured in certain other substances.

This is in perfect agreement with the generalisation we have already made that there are various definite levels of activity of an X-radiation in any substance, the level depending upon the whole of a more or less complex beam, and that a change of the activity in one substance from level to level may take place without the least indication of any corresponding change in a second substance. What we have now found is, that the penetrating powers of secondary and primary radiations are equal in some substances *subsequent* to transmission through plates of material which exhibit or produce the difference.

What then of Compton's hypothesis, and more important still, the second line obtained in the spectrum of the scattered radiation? Can the wavelength of a radiation change without producing a corresponding [illegible] orption in *all* substances?

In answer, we must point out that we have already demonstrated that a change in the activity (photo-electric action, ionisation, absorption) of a radiation can take place without a change in the wave-length—that wave-length and material substance are not the only factors in X-ray phenomena. In order to reconcile our experimental results with Compton's hypothetical change of wave-length, we should be compelled to go further and state that a change of wave-length may take place without a corresponding change in activity—that is, we should be obliged to dissociate the properties of an X-radiation from wave-length altogether, or at any rate we should have to assume that within certain limits, absorption, electronic emission, etc., are independent of wave-length.

Consequently we are very sceptical as to whether a change in the diffraction angle in spectroscopic measurements really does correspond to a change of wave-length. A measurement of absorption is purely experimental, but a measurement of wave-length is dependent on the adequacy of the classical theory of diffraction, and assumes the absence of any unforeseen phenomenon

It is an experimental fact that the critical condition which governs the change of activity which we have called the *J*-phenomenon is not wave-length, but something analogous to "temperature" of the whole beam of X-rays. Our critical condition for the excitation of the *J*-electronic emission, *J*-ionisation and *J*-absorption is not that the frequency of the primary beam should be higher than a certain critical value, but that this "temperature" shall be higher than a certain value. Thus in place of Stokes' Law which we found to hold for *K* and *L* radiations, we find that in the case of the *J*-phenomenon at least, we may write T_1 must be greater than T_2 where T_1 is the average penetrating power ("temperature") of the beam and T_2 is a penetrating power characteristic of the substance traversed. We use the term "temperature" only tentatively because it is a familiar physical quality which represents most closely, or is analogous to, the state of a complex radiation as measured by penetrating power by ionisation-absorption methods. It seems just possible that Stokes' Law may need to be re-stated in some such way in order to make it more general, and to express what is most fundamental. This, however, is speculative. the experimental facts we have recorded are in a different category altogether, they are beyond dispute.

To summarise, we must accept one of the following possible alternatives.

(1) The second spectral line in Compton's experiments does not represent another wave-length in the secondary radiation incident on the crystal of the spectrometer, or

(2) Wave-length may change without a corresponding change in the activity of an X-radiation This seems possible only on the assumption of the dual nature of radiation in some such way as is suggested by Sir J. J. Thomson, or

(3) The conditions essential to the production of the second spectral line in the spectrum of scattered X-radiation have not been realised in the hundreds of experiments we have made on the phenomenon. This is highly improbable both from the variety of our experiments and from the fact that we do under some conditions obtain what has the *superficial appearance* of a change of wave-length.

The alternative probabilities are thus reduced to (1) and (2)

The Energy Levels of the Carbon Monoxide Molecule.

IN a recent communication (NATURE, 116, 170, 1925) I gave formulæ for the two band systems (or "groups") associated with ionised carbon monoxide. These formulæ were afterwards verified (NATURE, 116, 207, 1925) by the discovery of "combination" bands due to the third possible transition between the three known energy levels These electronic levels may be called *X′*, *A′*, and *B′*, in order of increasing energy *A′* is a double level of spacing 126 cm $^{-1}$, while *X′* and *B′* are single. The *A′*-*X′* transition gives the comet-tail bands, the *B′*-*X′* transition the first negative group of carbon, and the *B′*-*A′* transition the new Baldet-Johnson combination bands

In an investigation on the excitation potentials of nitrogen bands, Duncan (*Astrophysical Jour.*, 62, 145, 1925) has observed four systems of bands which he considers to be new nitrogen band systems. I find, however, that his second negative group is the first negative group of carbon, just mentioned above, his seventh positive group is the fourth positive group of carbon, commonly attributed to carbon monoxide, and his fifth positive group is probably the third positive group of carbon, commonly attributed to carbon dioxide I have been unable to identify his sixth positive group. The second negative group is strong, and his value of the excitation potential is therefore doubtless reliable Applying the correction of 1 3 volts which I found necessary in the case of the known nitrogen band systems (NATURE, January 16, p 81), one obtains 19 8 volts for the energy of state *B′*. This gives 14 2 volts as the calculated energy of state *X′*, *i e.* the ionisation potential of CO. The best direct experimental values are 14 3 and 14 1 volts (see p 123, Report of National Research Council on "Critical Potentials").

When writing my letter on the band spectra associated with carbon (NATURE, 116, 170, 1925), I was unable to obtain any satisfactory quantum relations for the fourth positive group. The vibration frequencies of 500 and 3000 quoted there were based on the series arrangement of a portion of the bands of this very extensive system, made by Deslandres and by Lyman. I now find on re-examination of this matter that in this one instance Deslandres arranged the bands in sequences (corresponding to a given *change* in vibrational quantum number) instead of following his usual custom of arrangement in progressions. It is, however, possible to arrange this system in progressions, showing the usual numerical relations, and the new tabulation includes not only all of the bands arranged in series by Deslandres and by Lyman, but also all of Lyman's "fifth positive group" (*Proc. Amer Acad Arts*, 45, 315, 1909), and all of the remaining unassigned bands, with the exception of about a dozen very faint members Approximately 150 bands thus appear on the *n′n″* diagram, the most extensive band system known for molecules of this general type. The heads are given within the rather large limits of error (and with Deslandres' values raised 1 Å U., to be consistent with those of subsequent investigators) by the formula

$$\nu = 64{,}721 + (1499\ 28n' - 17\ 24n'^2) - (2147\ 74n'' - 12\ 703n''^2),$$

where *n′* varies from 0 to 14, and *n″* from 0 to 22. The distribution of intensity is similar to that in the familiar aluminium bands, which I have previously cited as typical (*Phys. Rev.*, 25, 240, 1925).

Investigators agree that this so-called fourth positive group of carbon, which seems always to appear in a vacuum tube discharge when stop-cock grease is used, is due to CO (see Kayser and Konen, vol. 7, p. 141), and direct evidence on this point is now available. Leifson, in an investigation of the absorption of some gases and vapours in the extreme ultra-violet (*Astro. Jour.*, in press), photographed a strong series of narrow absorption bands in carbon monoxide which I find represent, for *absorption*, the 0-0, 0-1, 0-2, etc. to 0-11 transitions, in my arrangement of the fourth positive group of carbon. Since the cold gas was used, only this one progression should appear This definitely establishes the final state of this system (in emission) as the stable state of the carbon monoxide molecule. Moreover, the *final* state of the Ångström CO bands is given by the same progression as the *initial* state of the fourth positive group. Thus the Ångström band heads can be represented by

$$\nu = 22{,}162 + (2158n' - 76n'^2) - (1499{\cdot}28n'' - 17{\cdot}24n''^2),$$

where n'' varies from 0 to 5 or more, and $n' = 0$, 1, and probably 2. This relationship places λ4511 as unquestionably the 0-0 band, a point concerning which there has been some dispute. (See Hulthén, *Ann. d. Phys.*, 71, 41, 1923, and Mecke, *Phys. Zeit.*, 26, 217, 1925.)

The system of electronic energy levels for carbon monoxide thus evaluated consists of X, A, and B for the neutral, and X', A', and B' for the ionised molecule. The transition A-X gives the fourth positive group of carbon, and B-A the Ångström CO bands. From the known structure of these latter bands, B and A are both single levels. The transitions for CO$^+$ have been given. Taking X as the zero level, the energy values of the various levels, in wave-numbers, and in volts, are approximately as follows:

$A = 64{,}721$ cm.$^{-1}$ = 8·0 volts,
$B = 86{,}883 = 10{\cdot}7$ volts,
$X' = 115{,}082 = 14{\cdot}2$ volts,
$A' = 135{,}554$ and $135{,}428 = 16{\cdot}7$ volts,
$B' = 160{,}720 = 19{\cdot}8$ volts.

The 0-0 band of the various systems should thus be excited at the following voltages: fourth group (λ1545) at 8·0 volts, Ångstrom bands (λ4511) at 10·7 volts, comet-tail bands (λ4880) at 16·7 volts, first negative group (λ2190) and "combination bands" (λ3974) at 19·8 volts.

Carbon monoxide is the only molecule, in addition to nitrogen, for which electronic energy levels of both the neutral and ionised state are known, and is the only molecule for which the spectroscopic data are complete. The new information now obtained leads to theoretical results of some significance. These are discussed in a letter on the "Structure of Molecules" to be published in another issue.

RAYMOND T BIRGE.

University of California,
December 19, 1925.

The Dynamics of Surface Action in Closed Vessels.

THE theoretical treatment which has been advanced, and experimentally tested, describing the effect of diluent gases and vapours on the initial stages of catalytic action (see NATURE, vol. 116, pp. 278-279), has been successfully extended to the dynamics of catalytic decomposition in closed vessels. Let $L.A \longrightarrow m.B + n.C + \ldots$, etc, be the reaction, and let $a, b, c, \ldots$, etc., be the initial pressures of the molecular species $A, B, C, \ldots$, etc., and let x be the pressure of A transformed in time t. At time t the pressure of $A = (a-x)$, of $B = (b + m/l.x)$, of $C = (c + n/l.x), \ldots$ etc., A gas stream of varying composition bombards the surface during the reaction, and the probability that a molecule A will hit a centre of activity immediately it becomes bare is given by the fraction of A molecules in the bombarding stream, *i.e.* by

$$\frac{\mu_A(a-x)}{\mu_A(a-x) + \mu_B(b + m/lx) + \mu_C(c + n/lx) + \ldots}, \qquad (a)$$

where μ_A, μ_B, μ_C are constants depending on the nature of the gas.

If $\tau_A, \tau_B, \tau_C, \ldots$, etc., represent the mean lives of the molecules $A, B, C, \ldots$ on the centres of activity which are assumed in the present argument to be homogeneous, ξ be the fraction of a given time interval t during which the centre is free of adsorbed molecules, and n be the number of molecules adsorbed during this time t, which number is equal to the number of times the centre becomes vacant, then the number of molecules of A that are present among the adsorbed molecules during t seconds

$$= \frac{n\mu_A(a-x)}{\Sigma\mu_A(a-x)}$$

and the time they occupy the centre is

$$\frac{n\tau_A\mu_A(a-x)}{\Sigma\mu_A(a-x)}.$$

Thus the fraction of the interval of t seconds during which the "centre of activity" is occupied by A is

$$\frac{1}{t}\,\frac{n\tau_A\mu_A(a-x)}{\Sigma\mu_A(a-x)}.$$

But
$$t = \xi + \frac{n\Sigma\mu_A\tau_A(a-x)}{\Sigma\mu_A(a-x)}.$$

Hence the fractional time during which the centre is occupied by the reactant becomes

$$\frac{\mu_A\tau_A(a-x)}{(\Sigma\mu_A\tau_A(a-x) + \xi/n\Sigma\mu_A(a-x)}. \qquad (b)$$

If k be a constant depending on the number and nature of the centres of activity present, then at constant temperature the rate of reaction may be calculated from the fractional times of occupation.

L-molecular Reaction.—The rate of reaction is proportional to the probability that l adjacent centres should be occupied simultaneously by the reactant. Thus

$$\frac{dx}{dt} = k \prod_{1 \longrightarrow l}\left(\frac{\mu_A\tau_A(a-x)}{\Sigma\mu_A\tau_A(a-x) + \xi/n\Sigma\mu_A(a-x)}\right) \qquad (1)$$

$$= k \prod_{1 \longrightarrow l}\left(\frac{\alpha(a-x)}{1+\beta x}\right) \quad . \quad . \quad . \quad . \quad . \qquad (2)$$

or
$$kt = \int_0^x \prod_{1 \longrightarrow l} \frac{1}{\alpha}\left(\frac{1+\beta a}{a-x} - \beta\right).dx,$$

where

$$\alpha = \frac{\mu_A\tau_A}{\Sigma\mu_A\tau_A a + \xi/n\Sigma\mu_A a}, \text{ and } \beta = \frac{\Sigma m/l\mu_B\tau_B - \mu_A\tau_A}{\Sigma\mu_A\tau_A a + \xi/n\Sigma\mu_A a}.$$

If $\xi/n\Sigma\mu_A a$ be independent of x, then the general solution is

$$k = \frac{A}{t}\log_e\frac{a}{a-x} + \frac{Bx}{t} + \frac{C}{t}\left\{\frac{1}{a-x} - \frac{1}{a}\right\} + \frac{L}{t}\left\{\frac{1}{(a-x)^{l-1}} - \frac{1}{(a)^{l-1}}\right\}, \qquad (3)$$

where A, B, C, . . . are constants. The special case $\beta = 0$ becomes

$$k = \frac{1}{(l-1)\ t \prod\limits_{1 \longrightarrow l} \alpha}\left\{\frac{1}{(a-x)^{l-1}} - \frac{1}{a^{l-1}}\right\} \qquad (4)$$

and is of the form followed by homogeneous reactions.

Uni-molecular Reaction.—In the great majority of surface actions the effect of the catalyst is to simplify the reaction, lower the heat of activation, and make the change uni-molecular. The general relation becomes

$$\frac{dx}{dt}=\frac{K(a-x)}{1+\beta x}, \quad . \quad . \quad . \quad (5)$$

and, when K and β are independent of x, integrates to

$$K=\frac{1+a\beta}{t}\log_e\frac{a}{a-x}-\frac{\beta x}{t}, \quad . \quad . \quad (6)$$

where

$$k=\frac{\mu_A\tau_A k}{\Sigma\mu_A\tau_A a+\xi/n\Sigma\mu_A a}, \text{ and } \beta=\frac{\Sigma m/l\mu_B\tau_B-\mu_A\tau_A}{\Sigma\mu_A\tau_A a+\xi/n\Sigma\mu^A a}.$$

The form of (6) varies markedly with the values of the constants, and the majority of the forms it can assume have been experimentally verified by Hinshelwood and co-workers in their experiments on the decomposition of gases on hot wires. I have repeated the experiments on the decomposition of nitrous oxide and ammonia by platinum, and find good agreement with (6). The dehydrogenation of ethyl alcohol by copper in closed vessels also follows this equation. It is to be observed that it is now unnecessary to assume that the surface is saturated to obtain relation (6). F. H. CONSTABLE.

St. John's College, Cambridge,
January 15.

Discovery and Dialectics.

PROF. MASSON, in NATURE of January 2, courteously dissents from the conclusions expressed in my "Science and Scientists in the Nineteenth Century," and, thanks to the courtesy of the editor, I am allowed to reply.

My proof-sheets were revised by seven Cambridge fellows, who were kind enough to give me the benefit of their accurate knowledge in the different departments of science with which I deal. In addition to them, Sir A. E. Shipley, Sir J. J. Thomson, Sir Joseph Larmor, and Sir Oliver Lodge read through my proofs and made many helpful suggestions. The last, in his Introduction, expressly agrees with my conclusion that there are every whit as many prepossessions in science as there are in theology. The warfare between science and theology is, therefore, in no wise unique; for a similar warfare is characteristic of *every* form of human knowledge.

This is my main thesis, and Prof. Masson does not seriously attack it. He does, however, dissent from my conclusion that men of science do not receive new ideas with enthusiasm, suggesting that if they oppose them they are the rank and file of the scientific army. Let us take, therefore, two outstanding contributions to knowledge, the conservation of energy and the evolution of species. Joule performed not merely one experiment but many experiments, and a man of the standing of Kelvin points out that scientists like Graham or Miller objected to the results of these experiments, saying "simply he did not believe in Joule because he had nothing but hundredths of a degree to prove his case by." Mohr, Mayer, and Helmholtz shared the keen hostility Joule encountered. Gustav Magnus warned Helmholtz against undue partiality for mathematics, and the attempt to bring remote provinces of physics together by its means. Poggendorf thought that the paper of Helmholtz on the conservation of energy was not worth publishing in the *Annalen*. The older physicists, like Dove and Reuss, would not admit the principle of the conservation of energy. Distinguished mathematical colleagues like Eisenstein and Lejeune-Dirichlet seconded the opposition of Dove and Reuss.

Darwin succeeded in obtaining the qualified approval of Lyell, Hooker, and Huxley to his illuminating conception. With these three signal exceptions, it is true to say that the leading men of the world of science offered the stoutest opposition to his ideas. Sir Richard Owen was a naturalist who occupied such a foremost position in science that he has been called the British Cuvier, and he could not see his way to accept the new view. Among the opposition were W. H. Harvey, J. H. Balfour, H. Falconer, Sir E. Sabine, H. C. F. Jenkin, St. G. J. Mivart, A. Gray, L. J. R. Agassiz, J. L. A. de Quatrefages de Bréau, G. A. Brullé, F. J. Pictet, J. H. C. Fabre, Henri Milne-Edwards, O. Volger, R. A. von Kölliker, and K. E. von Baer. The bulk of the criticisms given in my book appeared almost immediately after the publication of the "Origin of Species," and, I do not think that I have given any criticism of later date than the year 1864, within five years of its appearance. These critics leave on the mind of the candid reader the impression Huxley took the trouble to record in 1887: "There is not the slightest doubt that, if a General Council of the Church scientific had been held at that time (*c.* 1860), we should have been condemned by an overwhelming majority." In 1885 he wrote: "It is curious now to remember how largely at first, the (scientific) objectors predominated."

ROBERT H. MURRAY.

Broughton Rectory,
Huntingdon.

DR. MURRAY'S reply to my review makes me feel, like the Elephant's Child, "a little warm, but not at all astonished." For I have not been taken literally, and I wished to be. Nor, I think, has Sir Oliver Lodge; for, whatever opinion the words of his "Introduction" may cover, in them he most certainly does not "expressly agree" that science is as full of prepossessions as is theology; he presents Dr. Murray's conclusion and its consequence, but his personal verdict on the question of equality is withheld. So far am I from dissenting from Dr. Murray's statement that new ideas are not enthusiastically received in the scientific world, that I was at pains to emphasise this fact, and went further by asserting that this coldness plays an indispensable part in the method of science by counteracting hasty belief. That Dr. Murray neglects the fundamental value of decent scepticism is my main quarrel with him. Please, I did not suggest that only the rank and file pooh-pooh new ideas! I expressly included every one. In doing so, I propounded an idea, and Dr. Murray has unkindly blighted it by neglect; I said, "Moreover, no man of science, not even the greatest, has more than a short period in his life during which he is so free from human vanities that his discoveries are faultless and his opinions just." Dr. Murray implies that I called Joule's work "one experiment"; I said "one research."

I shall not, I hope, be thought guilty of impatience if, for the sake of saving space, I close by referring any one who wishes to concern themselves in these matters (*a*) to the literal sense of my article of January 2, (*b*) to Sir Oliver Lodge's Introduction to (*c*) Dr. Murray's well-founded facts about men of science, and (*d*) to Dr. Murray's natural, but—I am sorry!—fallacious inferences about science.

IRVINE MASSON.

Genes and Linkage Groups in Genetics.

I HAVE no intention of criticising in detail the elementary lecture on Mendelism which Prof Huxley gives in NATURE of January 30, p 154, as a supposed reply to my remarks in the issue of December 26, 1925 Our minds are so differently constituted that what he regards as facts I consider to be unproved assumptions, and what he calls proof I consider to be begging the question Nothing of what he says is new, indeed much of it, it has been my painful duty to present to my students year after year whilst never concealing from them my utter scepticism as to the assumptions involved.

Prof. Huxley's statistics leave me entirely unmoved Statistics in biology are a very dangerous weapon; their value entirely depends on the validity and definable character of the *unit* which is counted It is because I do not regard Morgan's units as having any validity whatever that I consider his deductions as valueless. These units are avowedly assumed in order to make his observations fit a preconceived theory, if the fit is not exact, then further units will be assumed in order to make the fit better, and this procedure he calls proof

I should like, however, a brief space to set forth to readers of NATURE the reasons why, in company with some of my most distinguished colleagues, I regard the whole of this "factorial analysis" as both formal and futile.

In the first place, the supposed "genes" or "unit factors," even if we concede their existence, throw no light whatever on the course of evolution or on the past history of existing species This is the opinion of those whose opinions are most entitled to respect in the realms of systematic zoology, of palæontology, and of embryology, which are the three great sources of our knowledge of evolution What is the use of telling us that the constitution of an animal is to be represented by the factors *a*, *b*, *c*, *d*, *e*, *f* and *g*, if it was not formerly represented by *a*, *b*, *c*, *d*, *e* and *f*, and has become what it is by the addition of "*g*"?—Yet when we examine in detail what the "factors" in Drosophila actually are, any competent entomologist would laugh to scorn the idea that they represent elements in the evolution of an actual insect. Secondly, what Morgan has proved in the case of Drosophila and what has been shown to occur in every case where plants are cultivated or animals bred in confinement in large numbers, is that sharp deviations from the type occur and that these aberrant individuals when crossed with the type exhibit Mendelian segregation in their inheritance So universally is this the case that geneticists like Baur have been driven to assume that there must be "idiokinetic factors" in the environment to account for these mutations

Now if the true object of science is *rerum causas scire*, once this fact has been well established, the next step should be to ascertain how the distinctive features of these mutations are acquired in the course of individual development and whether apparently unrelated mutations might not be due to varying intensities of the same disturbance of embryological processes As I pointed out in the review which originally excited Prof Huxley's criticism, we can show in the case of Vertebrata that "mutations" as apparently diverse in nature as mental defect and supernumerary fingers can be explained as due to varying degrees of abnormal amniotic pressure Yet we look in vain in the work of the Morgan school for any trace of analysis of this sort

Thirdly, when the course of individual development has been ascertained, the next step should be to try to find the environmental influences which have produced the disturbances of development. It is because Tornier has done this and has brought a great mass of direct and indirect evidence in support of his views that I regard his work as equal in value to that of all the other geneticists put together Not only has he shown how mutations arise, but he has also thrown light on the still more interesting question of why these mutants when exposed to natural conditions tend to revert to type. This valuable work is of course only in its initial stages like other pieces of important work, its course was interrupted by the War and has not been since resumed, but it is only along lines such as these and not by the assumption of imaginary factors that a ture explanation of the origin of mutations and of the physiological nature of Mendelian inheritance will ever be attained

E W MACBRIDE.

Greenland or Polar Front.

To Mr L C. W Bonacina's communication entitled "Greenland or Polar Front," which appeared in NATURE of November 21, p 748, I should like to make a brief reply I must again insist upon the contrast which exists between the two polar regions of the earth,[1] and repeat that, despite much misconception, the Arctic basin is neither cold nor dry relative to Greenland or, during the cold season, even to Siberia and British America Nansen's observations made during the drift of the *Fram* show that 66 5 days in the year were foggy Mr Bonacina's statement that fogs did not occur during the winter, does not refer to the long cold polar season, but to the short period of December to February inclusive Fogs occurred in every other month, and one day in every four was foggy for this period During Capt Amundsen's flight toward the Pole, fogs were so thick that little could be seen for much of the way, and near 89° N fogs were a serious handicap in taking off after the forced landing

Mr Bonacina urges in support of a supposed cold high-pressure "polar front" a pressure difference between the Arctic basin and the Icelandic low, but it is significant that within this very sector of the Arctic basin the dominant wind component along the meridian is not from the north, but from the south Mohn's tables based upon Nansen's observations on the *Fram* for the year 1895 (when the vessel zigzagged throughout along the 85th parallel of latitude within the European sector) showed that for the entire year 59 4 per cent. of the wind force had a southerly component and only 40 6 per cent a northerly Reckoned for the periods November to April and May to October separately, the corresponding figures are for the southerly component 58 1 per cent and 60 5 per cent respectively For the short winter season (December to February) when fogs were not observed and when, according to Mr Bonacina, it might be supposed that cold air would move out southward from the Arctic basin, no less than 63 2 per cent. of the wind component reckoned along the meridian was from the south[2] As pointed out in my earlier communication to NATURE, the most striking fact which emerges from all the *Fram* observations is their monotony of character with but slight seasonal changes—these are the well-known characteristics of an expanse of sea.

The course of the *Fram* as it drifted in the ice supplies an even more striking proof that the dominant winds over the Arctic basin do not move outward, but, on the contrary, inward. The wind components throughout have been computed by Mohn, and these appear strikingly set forth upon two of his charts.[3] Evidence has piled up along the same direction from stations on the Arctic coasts of Siberia and British America for the long winter season, during which winds from the north are accompanied by elevation of temperature and those from the south by a fall of temperature. Kindle, with much personal experience in Arctic America, has rendered a service through assembling the observations to prove this generalisation.[4]

The Palæolithic Drawing of a Horse from Sherborne, Dorset.

In entitling his account of this object "On an *apparently* Palæolithic Engraving on a Bone from Dorset" (my italics) Sir Arthur Smith Woodward displayed his habitual caution, and it is with great regret that I now find myself obliged to differ from one for whose judgment I have so great a respect. For I still believe the Sherborne drawing to be a forgery and a clumsy one at that. It was perpetrated as a practical joke, such as delight the heart of boys of fifteen. How far the finders of the bone were involved in the affair there is nothing to shew, one or other of them may have been innocent of it. But that some of the boys in the school were not quite so ignorant as Mr. Araldo Cortesi professes himself to be is shown by the fact that they were familiar with "Early Man in Britain" and the illustration of the Creswell Crag horse given there by Sir W. Boyd Dawkins.

Mr. Bayzand, who was intimately acquainted with all the facts—which he communicated to me—acutely remarks that a tracing of the Sherborne drawing when superposed on that of Creswell reveals an identity in size and as well a remarkable correspondence in outline. The odds against such a correspondence arising as a mere coincidence are sufficiently great, but it is easy to understand how a tyro in the art of forgery would have found it difficult—unless he happened to be a skilled artist—to make a sufficiently plausible copy with a change of scale. Further, those parts of the Sherborne copy which differ from the Creswell original do so in just those details which are likely to betray the inexperienced observer.

I do not fully understand the term "semifossilised," but I imagine it is intended to mean less altered than the mammalian teeth found in the gravels of the neighbourhood, *i.e.* in just such a state as might be expected of a bone which had lain in a refuse heap exposed to the air.

W. J. Sollas.

University Museum,
Oxford, January 22.

Prof. W. J. Sollas has directed my attention to a letter in the issue of Nature of January 16, by Sir Arthur Smith Woodward, on the supposed Palæolithic drawing of a horse from Sherborne.

At the time of the "discovery" of this drawing I was engaged at the Sherborne School in arranging the museum collections and then learnt something of the history of the find.

The whole affair, as I gathered, was a trick played solely for the benefit of the science master without any idea that it would go any further. Its success was a source of much merriment at the school, particularly amongst those boys who were under this master, and I was even invited by some to inspect the fake.

I may mention that a copy of "Early Man in Britain" was lying in the Museum while I was there, and I should add that I was informed that the bone was discovered near a rubbish heap on the Bristol road, where some of the refuse of the town had been deposited.

This, so far as I can remember, was in the year 1912 or 1913, and I dismissed the whole matter from my mind until I learnt, not without surprise, that Sir Arthur Smith Woodward had communicated the "discovery" to the Geological Society. When later I read his account I at once informed Prof. Sollas of all that I knew, and so am directly responsible for the statement made by him in the third edition of "Ancient Hunters."

C. J. Bayzand.

Oxford, January 21.

Spermatogenesis in Spiders and the Chromosome Hypothesis of Heredity.

Prof. Warren, in Nature, January 16, writes a second letter in support of his previous contention that the spermatogenesis of spiders is different from that of all other animals, and that it is "a good corrective to the view of the all-sufficiency of chromosomes, and to the tendency to substitute cellular structure in the place of the directive vital activity of the organism."

It is difficult to understand what Prof. Warren means by this statement, because it is universally allowed that modern cytological observations have thrown a clear light on nearly every problem of genetics and heredity.

In the past ten years I have probably carried out more investigations than any one else on the cell cytoplasm and its organellæ, yet throughout I have been obliged to admit that the only cell organs which fulfil the necessary conditions which a study of genetics lays down, are the chromosomes.

At the same time, while I have been forced to believe the chromosome theory in general, I recognise clearly that there are still many facts which the chromosome theory does not explain. The spermatogenesis of spiders, as we know it in this laboratory, provides no stumbling-block to a belief in any part of the chromosome theory, any more than does the presence of atypic spermatozoa in molluscs, for example.

The amitosis question has long been a subject which the anti-chromosome theorist has toyed. Prof. Warren is not the first rebel, he will not be the last. When I was a student at Oxford I caused some concern to my teachers by developing a bad attack of amitosis-itis. It was brought on by reading Prof. Child's interesting paper on "Moniezia." However, that is "past history."

Now Prof. Warren is in the middle of a bad attack of the same disease. Like all the evidence for amitosis in germ cells, Prof. Warren's is going to be unconvincing. Even if this investigator does demonstrate division or fragmentation of nuclei, this does not necessarily mean that the cell is dividing amitotically. I can only refer Prof. Warren to Macklin's paper in the Carnegie Institution of Washington, Series, Embryology.

[5] William Herbert Hobbs, "The Glacial Anticyclones, the Poles of the Atmospheric Circulation," *University of Michigan Publication*, Ann Arbor, Mich., pp. 200, 3 pls., 53 text figures. 3 dollars.

If the chromosome theorist can demonstrate one normal mitosis in Prof. Warren's slides, the whole of this observer's claims must be in doubt. The onus lies with Prof. Warren, and not with the chromosome theorist. The atypic sperms of molluscs have been followed even into the egg; no cytologist could sustain an attack on the chromosome theory when we know that the typic sperms of these molluscs are the real agents in fertilisation.

As was reported in NATURE in October 17, 1925, Dr. S. D. King examined one species of spider, and found a normal chromosome cycle in certainly a vast majority of the cells. In fact, I have never seen a bigger X-chromosome Now, we know from Dr. King's work that a normal chromosome cycle may occur in spiders, with normal spermatogonial divisions and normal spermatogonial spindle-bridges, so we must hesitate in accepting Prof. Warren's statements so far as they constitute an attack on the chromosome theory.

Prof. Warren seems to have been the first person to have shown that peculiar atypic spermatogenesis may occur in spiders, and for this he deserves much credit.

Polyploidy and Sex Chromosomes.

THE interesting announcement of Dr. J. W. Heslop Harrison (NATURE, January 9, p. 50) that he has found a single pair of sex chromosomes in certain polyploid species of Salix will, if confirmed, add to our knowledge of sex chromosomes in diœcious plants, but does not necessarily alter any of the current views regarding the origin of polyploidy. The fundamental fact that the chromosomes in many plant genera occur in arithmetical series, shows that the process of multiplication in number is one that affects all the chromosomes simultaneously. This is true however the change comes about, whether, for example, through a suspended mitosis or by the union, in hybridisation, of nuclei the chromosomes of which are sufficiently incompatible to be unable to pair in the following meiosis. Multiplication of the whole chromosome series through a condition involving a suspended mitosis is well known to occur naturally in various plant tissues and has been produced experimentally by a variety of methods.

There has been evidence for many years, for example, in the genetic behaviour of *Oenothera gigas*, that secondary changes took place in addition to the primary doubling of the chromosome number, such changes being either coincident with or subsequent to the original doubling. The hypothesis ("Polyploidy," 1924, *Brit Journ. Exp. Biol.*, vol. 1, p. 175) that the hexaploid condition in wheat has arisen through the crossing of a diploid with a tetraploid species, producing a sterile F_1, in certain individuals of which a split in the chromosomes gave all the chromosomes mates and so produced a fertile hexaploid individual, has recently been fully confirmed experimentally (Clausen, R. E., and Goodspeed, T. H., "Interspecific Hybridisation in Nicotiana," *Genetics*, vol. 10, p. 278, 1925). In a cross between *Nicotiana tabacum* var. (diploid, $n=12$ chromosomes) and *N. glutinosa* (tetraploid, $n=24$ chromosomes) they obtained a sterile F_1 with $3n$ (36) chromosomes. A single capsule, however, produced from seeds two plants, one of which was fertile and when selfed produced an F_2 population like the F_1 but somewhat larger in size. These were shown to be hexaploid ($2n=72$), although the authors speak of it as a tetraploid form.

This removes any possible doubt about such processes actually taking place and affecting all the chromosomes simultaneously. If a single pair of sex chromosomes occurs in a hexaploid species of Salix, it would mean that an additional process of adjustment has taken place, the nature of which might be disclosed by further investigation. There is evidence that secondary changes have taken place in the chromosomes of certain polyploid species. The size relationships of chromosomes and nuclei in the Salices have already shown that some peculiar conditions are involved, and these may well be concerned in part with the readjustment of the sex chromosome mechanism.

Two further points must be briefly stated in this connexion. (1) Bridges (*Amer. Nat.*, vol. 59, p. 127) has recently obtained tetraploid females of Drosophila with 4 sex chromosomes, showing that the X-chromosomes have been duplicated at the same time and in the same way as the autosomes. (2) The situation which Dr. Harrison mentions has already been described (Santos in *Bot. Gaz.*, vol. 75, 1923) in Elodea. This is tetraploid in comparison with related forms, having 48 chromosomes including an unequal XY pair. Meurman (*Soc. Sci. Fennica, Comm. Biol.*, 2, 3) has also recently given reasons for suggesting that *Rumex acetosella* ($n=20$-21) is a ditriploid species. It has a single pair of sex chromosomes and another pair which are transitional in behaviour between sex chromosomes and autosomes. These are further reasons for believing that sex chromosomes duplicated in the process of tetraploidy can later be gradually transformed into autosomes.

The Magnetic Storm of January 26-27, 1926.

THE great increase in solar activity since the middle of November last, as manifested by spots and faculæ, was not accompanied by any notable magnetic disturbances until January 26, when the greatest storm of the present solar cycle was recorded.

There is some ground for considering this storm as one of a sequence of disturbances at approximately 27-day intervals, extending with only three interruptions since March 5, 1925, but this is not yet definitely established.

There was a small "Sudden Commencement" at $17^h\ 30^m$ on January 25, but it is uncertain whether this should be associated—except as a premonitory symptom—with the storm proper, which may be considered as beginning on January 26, with pronounced movements in both D and H at $15^h\ 30^m$. The general character of the disturbance followed a normal course, with an extreme range in D of 74′, and in H of 660γ.

An interesting feature of the H record was a periodicity in the recurrence of maxima in the first phase of the storm. Four conspicuous maxima were found to be spaced at intervals of exactly 54 minutes, whilst midway between the last two was the highest maximum of the storm. Further examination of the curve suggested the superposition of two periodicities of about 18 and 27 minutes respectively. This was tested by measuring the times of all the more obvious maxima in this portion of the curve, when it was found that during a period of three hours there was a maximum corresponding to every integral multiple, from 0 to 10, of 18^m, whilst all the principal maxima corresponded to integral multiples of 27^{m}, and all except the greatest, to the concurrence of integral multiples of both periods. This exception may seem to vitiate the whole conception of the double periodicity suggested, but the objection disappears when it is remembered that an impulse may be periodic without its amplitude factor being a constant, and it only requires a suitable adjustment of the values of these factors for the maximum of the 27 minute period to more than neutralise at this one point the minimum of the 18 minute period. There are also many other oscillations of short period present which must necessarily modify the absolute values of maxima.

This double periodicity may be accounted for, if we suppose the magnetic disturbances to be due to ionic emissions from the sun, propagated in rays with approximately equal spacing, whilst the density of the ions varies in a periodic manner, in shells along the rays, owing to a pulsating or rhythmic emission from the disturbed region on the sun. In this way the orbital motion of the earth, entering the successive rays, would account for one period, whilst the arrival of successive shells at the earth's position would account for the other, and variations in the degree of concentration in both rays and shells would account for any variations in amplitude, as well as for the presence of minor oscillations concurrently with those presenting the more conspicuous features of the record.

Use of Interference Methods in the Determination of Stellar Diameters.

Referring to the article on the work of Prof. Michelson in Nature of January 2, it is interesting to note that the first suggestion as to the application of interferential methods to the determination of the angular diameter of stars appears to have been made in 1868, being due to Fizeau, and that the method was actually put to the test in France—although with negative results—seventeen years before Prof. Michelson's paper of 1910 referred to by Sir Oliver Lodge. Pointing out a relation between the width of the interference bands and the dimensions of the source of light, Fizeau added this pregnant remark: "It is perhaps permitted to hope that by taking this principle as a basis, and in forming, for example, by means of slits wide apart, interference fringes at the faces of large instruments intended for stellar observations, it will become possible to obtain some new data on the angular diameter of the stars" (*Comptes rendus*, 5, 66, 1869, p. 934).

In the absence of any telescope of sufficient size, this suggestion was bound to remain barren for more than fifty years, but the method was nevertheless actually used in Marseilles in 1873, by Stephan, with a telescope of 0·80 metre aperture, for the purpose of measuring stellar diameter. The aperture was, however, too small, and Stephan had to be satisfied with ascertaining that the apparent diameter of stars of the first magnitude, including Sirius, is less than 0·158″ (*Comptes rendus*, 5, 76, 1873, and 5, 78, 1874, p. 1008).

The first successful application (to the measurement of the diameter of the satellites of Jupiter, of the order of about 1″) was made by Prof. Michelson in 1891, but, by an improvement of the method, Hamy in Paris measured in 1898 the apparent diameter of Vesta (0·54″).

As we all know, the prize fell finally to the hands of the American astronomers, thanks to the amazing self-confidence and tenacity of purpose, combined with almost superhuman skill, which rendered possible the adjustment of mirrors, some twenty feet apart, to an order of displacement comparable to the wave-length of light.

The fame of Prof. Michelson is so well established, and the results themselves are so striking and far-reaching, that the above acknowledgment of the efforts made elsewhere, sterile, it seems, only because of the modest equipment available, in no wise diminishes the glamour of the final achievement.

M. Gheury de Bray.

The Free Path of Slow Protons in Helium.

In the issue of Nature for December 19, p. 900, Dr. A. J. Dempster states that he has found that slowly moving protons pass almost freely through helium atoms without being neutralised. In this connexion it may be of interest to state that I have found in the course of experiments on the scattering of protons (hydrogen positive rays) by helium and other gases, that the scattering in helium is a maximum for rays of the energy of about 10,000 volts. For slower rays the scattering is less, and for rays of 3500 volts, the slowest examined, is about 75 per cent. of the maximum. While these rays are considerably faster than those used by Dempster (300 to 900 volts), both results are probably part of the same effect. This may be analogous to the abnormal penetration of very slow electrons through certain gases found by Ramsauer. The *velocities* of these electrons were about the same as those of the protons used by Dr. Dempster. The effect was most marked in argon, but also occurred in helium and neon.

Results on the scattering of protons in hydrogen, now awaiting publication, do not show this abnormality, the scattering increasing with decreasing energy of the rays, though less rapidly than would be expected if the scattering were due to forces of the inverse square type. Experiments on argon are in progress.

Residual Ionisation in Closed Vessels.

Experiments have frequently been carried out to determine the residual ionisation in closed vessels, and to reveal the conditions under which this is a minimum. One of the lowest values hitherto measured is that of McLennan and Murray, who made their measurements over Lake Ontario, using an ionisation chamber of ice. They obtained the value $q=2{\cdot}6$ pairs of ions per c.c. per second.

It seems to have escaped notice that K. Bergwitz ("Elster-Geitel Festschrift," p. 585 (1915)) has made measurements in rock-salt workings in Germany, when he found the exceedingly small value of $q=0{\cdot}8$.

The value of the residual ionisation has a significance in connexion with estimates of the contribution of the penetrating nebular γ-radiation to atmospheric ionisation, and I have not seen a reference to Bergwitz' result in recent publications on this subject. This is undoubtedly due to the fact that the above-mentioned publication is not so well known as it deserves to be. It commemorates the sixtieth anniversary of those two distinguished and inseparable German scientists, Elster and Geitel, and contains many valuable contributions to radioactive literature.

Light Waves and Light Corpuscles.

By Prof GILBERT N. LEWIS, University of California.

THE theory that light is a series of spherical waves progressing from the source with velocity *c*, and the theory that light is a group of corpuscles moving in straight lines from the source with velocity *c*, have seemed mutually incompatible. Yet we must inquire whether this apparent incompatibility may not be due to some error in our traditional modes of thought, for no prediction of either of these two theories has yet failed to be confirmed. Indeed, we have reached the point where it seems justifiable to summarise a part of our information regarding light in the following manner.

LAWS OF THE CORPUSCLE

Recent experiments, especially those of A. H. Compton, have fully corroborated Einstein's brilliant surmise that the energy of radiation consists of quanta. Thus the energy lost by an emitting atom travels as a discrete particle along a single continuous path with the velocity *c*. This path is a straight line, except for deflexions in the immediate neighbourhood of another mass In the process of deflexion the particle of light and the other mass both obey in detail the laws of conservation of energy, mass, and momentum. If in Fig. 1 a corpuscle of light proceeds from *S* to a mirror at *A* and then to an absorbing screen at *D*, we are convinced that the time required for the corpuscle to pass from *S* to *D* is very nearly the length of the path *SAD* divided by *c*. But we are also convinced that the corpuscle never moves with a higher velocity than *c*, and therefore its path must be very nearly the two straight lines *SA* and *AD* This law of the rectilinearity of the path will be very important in our further discussion.

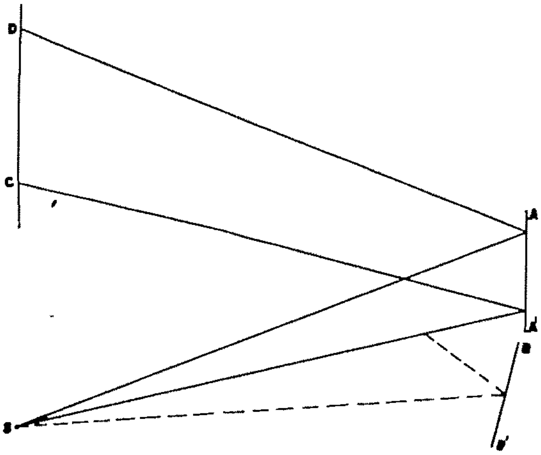

FIG 1

LAWS OF INTERFERENCE.

The classical laws of interference maintain their full validity no matter how weak a source of light is employed. Thus if we should set up an optical apparatus to give light and dark interference bands upon a screen, even if the source of light were so extremely weak as to give only one atomic emission per hour, yet in course of time a photographic plate placed at the screen would show the typical bright and dark bands. The phenomenon of interference can, therefore, in no way depend upon any mutual interaction of a number of quanta, but each quantum by itself must obey, at least statistically, the laws of interference

Let us suppose that the optical apparatus consists of a pair of Fresnel mirrors, as shown in Fig 1. *S* is the source of light, and *AA'* and *BB'* are two mirrors producing interference bands on the screen *CD*. Now if the emitting source *only* sends out quanta, some of which reach the screen by way of one mirror and others by way of the other mirror, it would be impossible to understand how the presence of one of the mirrors could affect the paths of the quanta reflected by the other mirror. We are, therefore, led irresistibly to the conclusion that the phenomenon of light cannot be completely described as an emission of discrete quanta of energy. In addition to this, there must be something which may provisionally be called an interference field, perhaps existing even at times when the transfer of energy is not occurring, which determines where the emitted corpuscles will be absorbed.

This idea that radiation must be resolved into its two aspects, one relating to an interference field and the other to an actual transfer of energy, has been advanced by Slater,[1] and later by Swann,[2] both of whom assume that the emitting atom produces a sort of "virtual" Poynting vector, that the corpuscle of light can travel only along the path of a Poynting vector, and that the intensity of the Poynting vector determines the probability that a quantum will travel by a given path.

This explanation, however, encounters difficulties, of which the chief one is that in the region of interference the path of the Poynting vector is not a straight line but a wavy one, and a corpuscle forced to travel along this path would be quite appreciably retarded. Thus the law of the linear path excludes the possibility that quanta follow the Poynting vector

Nevertheless, if we are to admit that the quanta travel from source to mirror and from mirror to screen in straight lines, the angle of incidence being equal to the angle of reflection, we are led to certain conclusions which at first sight seem absolutely indefensible. If the mirrors are so arranged that the point *C* lies in the centre of a dark band, then no quanta will start from the source in the direction *SA'*. But suppose that *S* is a distant source, and that the quanta are on their way before the mirrors are set up, how can the presence of the mirror *BB'* prevent the light corpuscles already on their way from *S* to *A'* from reaching the forbidden spot *C*? Do the emitting atoms know *in advance* how the mirrors are going to be arranged, and refuse to emit in the directions which would lead to the dark bands? Or, in other words, can we, by setting up such a simple interference system, alter a past event, such, for example, as a star's emission of a quantum in a certain direction some thousands of years ago? Such a thought is repugnant to common sense, and yet, absurd as it may seem at first sight, it is essentially the theory which I now wish to propose. I shall attempt to show that such a theory requires only a slight extension of the idea of physical time introduced by Einstein, and that it leads to a far better agreement between physical concepts and the geometry which interprets so satisfactorily the kinematics of relativity. By way of introduction, let us consider briefly the meaning of time in the physical sciences.

---

[1] Slater, NATURE, 113, 307 (1924)

[2] Swann, *Science*, 61, 425 (1925)

THE IDEA OF TIME IN PHYSICS.

There is some discrepancy between the equations of mathematical physics and the less formal physical explanations with which we are accustomed to annotate them. The equations themselves recognise no distinction between positive and negative extension in time; they are symmetrical. But, in the language of physics, a great distinction is made between past and future. Yet the eclipses of a thousand years ago are calculated with just the same precision as those of a thousand years hence, and (except for slight tidal action) a moving picture of the solar system, if the film were run backward, would show a system equally in accord with the laws of Kepler, Newton, and Einstein.

In daily life we constantly recognise the uni-directional character of time, but here we deal with far greater complexity than is found in the simple systems of physics and chemistry. Is it necessary or useful in these sciences to assume any dissymmetry between past and future?[3] At first we should be inclined to say that there must be such dissymmetry in the so-called irreversible processes, but Gibbs and Boltzmann have taught us to regard these merely as an enormous number of elementary processes, each of which obeys simple mechanical laws.

However, the idea that elementary processes, involving only a few atoms or molecules, are in all respects reversible, has never been fully accepted; for while it is admitted that the motion of the atoms in their collisions with one another may be perfectly reversible, it has seemed that the process of *radiation*, even from a single atom, must be irreversible. Indeed, so long as it was supposed that a radiating atom sends out energy in all directions, there seemed to be no way of regarding such a process as reversible. But we now know that this is not the case, and in advancing the theorem of 'entire equilibrium,' I have recently shown[4] how we may consider all these elementary processes as completely reversible and symmetrical with respect to past and future. We thus arrive at the view that a corpuscle of light is shot out from an atom, as an electron may be ejected; that this corpuscle then travels about and later reaches another atom where it is absorbed, by a process which is the exact reverse of the process of emission. I desire now to go much further than this, and to point out an essential difference between the emission and later absorption of an electron and the emission and absorption of light. Here it will be necessary to recall some of the salient features of the geometry of relativity.

THE GEOMETRY AND THE PHYSICS OF RELATIVITY.

The new kinematics is so admirably represented by the geometry introduced by Minkowski[5] that we should spare no effort to secure harmony between the ideas of this geometry and the concepts of physics. Let me first point out how absurd it would be in any geometry to find a theorem true for a given figure, but false if the figure were turned upside down. In showing that all processes, including radiation, are perfectly symmetrical with respect to past and future, an important step has been taken toward reconciling our physical and geometrical ideas.

Next it may be noted that radiation occupies a unique position in kinematics. In the two-dimensional geometry of relativity, illustrated in Fig. 2, there are two singular lines through a point O, namely, OL and OL', which separate all of the space-like lines, such as OX and OX', from all time-like lines, such as OT and OT'. The singular lines occupy an intermediate position and belong no more to one class than to the other. Now a line such as OT or OT' may be regarded as a locus in space-time of a particle, but lines such as OX and OX' can have no such interpretation. When we associate the singular line OL with the time-like lines, and say that it represents the motion of a light particle, we are forsaking the symmetry of the geometry as a concession to certain habits of thought. If we continue to make this concession, it must be met with a realisation of the unique character of the radiation process.

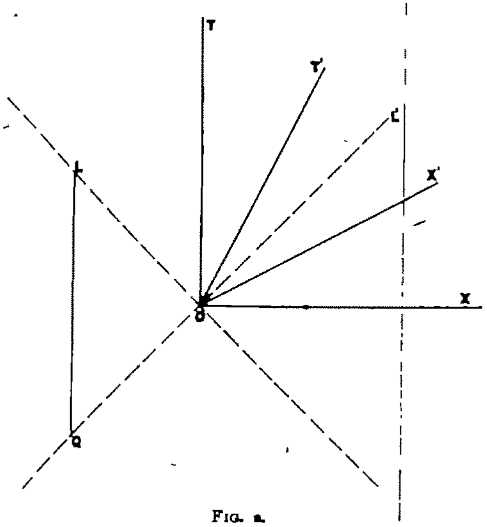

FIG. 2.

It is characteristic of this geometry that any interval such as OL, along a singular line, is said to have zero length, and this is an idea of which much use has been made in the mathematics but none in the physics of relativity. Let us now say that if OT and QL represent the loci of two atoms, then any pair of points, such as O and L or O and Q, which are separated by zero distance are in ***virtual contact***. In other words, I may say that my eye touches a star, not in the same sense as when I say that my hand touches a pen, but in an equally physical sense.

---

[3] This is a subject which I have discussed at some length in the recent Silliman Lectures, which will be published shortly by the Yale Press.

[4] *Proc. Nat. Acad. Sci*, 11, 179 (1925); 11, 422 (1925).

[5] This geometry has been worked out in some detail by Prof. E. B. Wilson and myself, *Proc. Amer. Acad*, 48, 389 (1912).

A NEW CONCEPTION OF LIGHT.

It has been generally assumed that a radiating body emits light 'into space' regardless of whether there are near or distant objects which may ultimately absorb that light; but, so far as I am aware, the only evidence for this view is the qualitative observation that on a clear night objects radiate energy into what seems to be empty space. This, however, might merely indicate that there is a considerable amount of cold matter in the universe. It would be interesting to make some quantitative experiments in this direction.

I shall make the contrary assumption that an atom never emits light except to another atom, and that in this process, which may rather be called a transmission than an emission, the atom which loses energy and the atom which gains energy play co-ordinate and symmetrical parts.

When two molecules collide and one gives up an atom or an electron to the other, we think of the process as occurring without mediation of any kind, and so probably we shall eventually consider the exchange of energy between two atoms through virtual contact. But to adopt this view at once would be severing too abruptly all connexion with the historical views of physics. We therefore say that a corpuscle of energy travels with the velocity *c* from atom to atom, and that there is a field (a 'retarded' field if ascribed to the emitting atom, an 'advanced' field if ascribed to the receiving atom) which determines the probability of the interchange. The invention of the corpuscle of light and these fields permit us to express the process of radiation in conformity with our ordinary spatial ideas and with the laws of conservation.

However, if the theory that I propose is correct, it should later be possible to express the probability of an energy transfer merely as the degree of 'fit' between the emitting and absorbing atoms at their points of virtual contact. The great revolution in physical thought which resulted from Maxwell's electromagnetic theory of light made scarcely any change in the mathematical equations of optics; and it is also possible to derive the same equations in accordance with the new views which I am here advancing. How this may be done will be set forth in a series of papers in the *Proceedings of the National Academy of Sciences*, of which the first is now in press.

Before concluding, I may point out that there is a crucial experiment, apparently within the range of experimental feasibility, which should decide for or against the theory. In the apparatus described in Fig. 1, all previous theories of light would predict a practically constant radiation pressure over the mirror *AA'*. This is true of the theories of Slater and of Swann; for the Poynting vector is uniformly distributed over the mirror. But suppose that the mirror *BB'* is so adjusted that the point *C* is in the centre of a dark interference band, while the point *D* is at the centre of the next bright band. Then, according to the new theory, quanta are travelling by the path *SAD* but none by the path *SA'C*; therefore the pressure on the mirror will all be on the side *A*, and if the mirror is suspended at its centre it will experience a measurable torque.

Climate Changes in Western America.[1]

It is now more than ten years since Ellsworth Huntington first employed the growth rings of the Big Trees of California to demonstrate the existence of variations of rainfall during the past four thousand years. The chief difficulty has been the conversion of the curve of tree-growth into a curve of rainfall. Trees grow more rapidly when they are young than when they are middle-aged, while in old trees the growth becomes irregular, so that the equation connecting tree-growth and rainfall at the present day cannot be applied with safety to the early rings of the very oldest trees. Huntington, fresh from an investigation of climatic changes in western Asia, read into the tree-growth curve a close similarity to the fluctuations of level of the Caspian, and applied a "Caspian correction factor" to the curve of tree-growth. The early levels of the Caspian are themselves very problematical, however, and the extrapolation to Western America did not inspire confidence.

A more trustworthy control has now been supplied by the variations in the level of the salt lakes of the Great Basin in close proximity to the trees. It is well known that during the Pleistocene Ice Age the Great Basin was occupied by a number of lakes, of which the largest have been termed Lakes Bonneville and Lahontan. This was many thousand years ago, but some investigations carried out by J. Claude Jones into the salt content of Lakes Pyramid and Winnemucca, which occupy part of the old basin of Lake Lahontan, show that these lakes have been accumulating salt for a period probably between 2500 and 3000 years, so that at some date between 1000 and 500 B.C. they consisted of fresh water. A lake formerly salt may become fresh either by overflowing or by becoming dry for a period long enough for the salt deposit to be covered by a thick layer of detritus. There is no evidence that the lakes have ever overflowed, so that we must adopt the second alternative and suppose that a long dry period ended between 1000 and 500 B.C. If J. C. Jones had left the matter there he would have done much to assist the study of climatic changes, but unfortunately he has confused the deposits of the old Pleistocene lake Lahontan with those of the modern lakes, and has marred his work by some unwarranted statements as to the survival of the lion, horse, and camel in North America into historic times.

In the same publication, E. Antevs has made a thorough revision of Huntington's data of tree-growth, and has prepared a series of curves corrected for the various sources of error, from intrinsic evidence only. His various curves for damp and dry localities agree well among themselves and seem to establish the reality of the climatic fluctuations, though they still leave the absolute level of the early part of the record in some doubt. These curves point to a rapid increase of rainfall about 850 B.C. This evidently corresponds with the formation of the modern Lakes Pyramid and Winnemucca; about that date the rainfall must have increased from less to more than its present value, and we can adjust the level of Antevs' curves accordingly. Various other points can be determined from a study of the terraces formed during different stages in the history of these and other lakes; for example, the salt content of Owens Lake shows that it became fresh rather more than 2000 years ago, in this case by rising to such a high level that it overflowed, indicating that a peak on the corrected tree-growth curve at 450 B.C. was the absolute maximum of the whole curve. The age of Lake Walker is estimated as 800 to 900 years, and it can be shown that this lake originated with some changes in the drainage during a period of increased rainfall. A peak on the tree-growth curve fixes this maximum, second only to that of 450 B.C., at A.D. 1000. The corresponding high-level beach can be recognised in the Lahontan basin, and we find that between these two maxima, sub-aerial deposits extended below the present level of Lakes Pyramid and Winnemucca, pointing to a rainfall below the present; the tree curve dates this as A.D. 650 to 850. Finally, a tree killed by the rising salt water of Lake Mono was 500 years old, showing that the rainfall has been slight since A.D. 1400.

---

[1] "Quaternary Climates: Geologic History of Lake Lahontan," by J. Claude Jones; "On the Pleistocene History of the Great Basin," by Ernst Antevs, "The Big Tree as a Climatic Measure," by Ernst Antevs, "Tree Growth and Climatic Interpretations," by Ellsworth Huntington. (Publication No. 352.) Pp v+212+10 plates. (Washington: Carnegie Institution, 1925.)

This comparison of two different sets of data gives a rainfall curve which can apparently be accepted with a good deal of confidence. Huntington, however, adopts a different interpretation: he considers that the long dry period preceding the formation of Lakes Pyramid and Winnemucca is the American representative of his Caspian drought of A.D. 650, and to make the dates fit he arbitrarily reduces Jones's determination of the age of these lakes by one-half. He states that "that is the earliest time when there is any evidence of so dry a period within historic times"; but it happens that there is abundant evidence of a prolonged dry period in Europe ending in 850 B.C., agreeing remarkably well with the combined evidence of the lakes and the trees in America.

News and Views.

WE record with deep regret the death on February 8, at sixty-four years of age, of Dr. W. Bateson, F.R.S., Director of the John Innes Horticultural Institution and past president of the British Association; also of Dr. W. E. Hoyle, formerly Director of the National Museum of Wales, on February 7, at seventy-one years of age.

UNDOUBTEDLY the best-planned museum in the British Isles, and one of the best in the world, is the National Museum of Wales. It is therefore regrettable that the completion of the Museum should so long have been delayed by unforeseen financial difficulties. The Council in its eighteenth annual report announces that further grants from H.M. Treasury for building purposes are contingent on the collection of considerable sums from other sources, and it therefore again appeals for the sum of 55,000*l.*, so that, with proportionate aid from the Treasury, at least the existing portion of the building may be completed and thrown open to the public. The donations to this end during the past year have been singularly few, but include 1500*l.* from Sir Wm. Reardon Smith and Lady Smith, as an instalment of their latest promised contribution of 5000*l.* Are there not among zoologists and museum men, several who would gladly give a trifle in recognition of the splendid work accomplished for this Museum by their old friend and colleague, the late Dr. W. Evans Hoyle? Now, under a Director energetic in another branch, archæology, especially in the field, bulks largely in this report. The excavation of the suburb of the Roman fort Y Gaer, near Brecon, also the investigation of Offa's Dyke and Watt's Dyke, are of particular interest. Among important additions is the botanical collection made by the late J. A. Wheldon of Liverpool, particularly rich in mosses, liver-worts, and lichens. But perhaps the most interesting paragraph of this report is that which tells how a summer school for museum curators was held at the National Museum last June and attended by sixteen representatives of twelve Welsh museums. The two days' course proved so successful that it is likely to be followed by another during the present year.

THE economic organisation and conditions of primitive peoples have been somewhat neglected by economists. Articles on the subject, however, have been included in the January supplement of the *Economic Journal*—the first of a series to be devoted to economic history. Prof. Muntz, of New York University, treating of the early development of economic concepts, selects Africa for his examples. There, he says, the vast majority of the native tribes were well acquainted with trade in some manner or another before contact with Caucasian peoples. Some tribes specialised in the manufacture of cotton goods, others in iron work; some were primarily agricultural, others pastoral, while in the forest many groups were in the hunting stage. The Bushmen and Hottentots had little or no notion of commercial exchange, though the latter had flocks and herds, could forge iron, and manufacture pottery. The most primitive form of peaceful exchange was that by means of reciprocal gifts, which were customary among the Bihénos and other tribes. Dumb barter or silent trade was carried on in many parts, as, for example, by the pigmy race of the Batuas or Akkas. Certain tribes, however, seem to have passed beyond the crude stage of barter. Salt formed a medium of exchange among the Latoukas, on the west coast and even in the interior. Indeed, throughout Africa the expression "a salt-eater" designated a rich man. Cowrie shells were employed for smaller transactions.

IN another article in the *Economic Journal* for January, Mr. Raymond Firth describes the primitive industries of the Maori. The unit was the village group, consisting usually of persons united by ties of kinship. Only the tattooer, the carver, or the tohunga (priestly adept) would be specialists, though some of the men might devote particular though not exclusive attention to one task. Barter with other tribes was always a matter of ceremonial exchange of gifts; haggling or bargaining was not tika (i.e. etiquette). An adequate return for a gift, however, was expected, and if it was not given would be a subject of comment. So, after all, it would appear that "homo œconomicus" was latent if not active. Industry was largely organised on a communal basis, and the products of fishing or the chase were added to the communal larder. Likewise agriculture, house building, or the felling of trees, was communal, though the right to private property was recognised where things such as fish-hooks, tools, pigeon troughs, etc., were made by an individual.

During November and December, Mr. E. H. Embree, Director of the Division of Studies of the Rockefeller Foundation, and Dr. Clark Wissler, head of the Department of Anthropology in the American Museum of Natural History, visited the eastern universities of Australia inquiring into plans for the energetic prosecution of anthropological work on the mainland and in the Pacific islands under Commonwealth administration. Last year the Foundation expressed itself as warmly interested in this work and appreciative of its urgency, and, although the visitors have not been in a position to make specific promises of financial support, their visit has greatly increased the probability of immediate and hearty co-operation between Australia and the United States in developing a campaign of work. It is understood that Mr. Embree and Dr. Wissler incline to the view, which is also fairly general in Australia, that anthropological work on the mainland should remain in the hands of individual workers or groups in the several States, but that the work in the islands should be organised from the new School of Anthropology in the University of Sydney, under the advice of a representative Australian board or council. It is expected that Prof. A. Radcliffe-Brown, who will be the first occupant of the new chair, will visit Washington on his way to Australia to confer with the officers of the Foundation.

Prof. A. Radcliffe-Brown, who has now relinquished his appointment of professor of anthropology in the University of Cape Town on his appointment to the newly instituted chair of anthropology in the University of Sydney, will arrive in England in the course of February. Before proceeding to Australia he will deliver a course of three public lectures at the London School of Economics, Houghton Street, Aldwych, W.C.2, on March 10, 12, and 15, at 3 P.M. The subject of the lectures will be "The Study of Backward Peoples: its Method and Practical Value." The series promises to be of considerable interest, as the subject is one on which Prof. Radcliffe-Brown is known to hold strong and original views. Admission to the lectures is free and without ticket.

At a meeting of the Linnean Society on January 7, Prof. F. Wood-Jones gave a brief account of the fauna and flora reserve on Kangaroo Island, South Australia. This reserve—known as Flinders Chase—comprises some 200 square miles at the western end of the island. It was set aside as a sanctuary by the Government of South Australia by Act of Parliament in 1919. The administration of the reserve is carried out by a small Board which has to raise funds for the Chase, the Government granting a pound for pound subsidy. It is intended that the reserve shall function not only as a sanctuary, but also as a depot for the legitimate supply of scientific material to workers in Australia and other lands, and for the furnishing of living animals to zoological gardens, specimens to museums, and pelts to the fur market. In this way the Board is confident that ample revenue can be raised for much needed work upon the Chase, and, granted a continuance of public goodwill and proper political support, it may be safely predicted that Flinders Chase will rank among the important sanctuaries of the world, and be a cherished possession of South Australia. Considerable progress has already been made in the direction of introducing on the Chase those species which are in most immediate danger of extermination in continental Australia, and this policy will be steadily continued so far as opportunity and funds permit. At the conclusion of the meeting, a resolution was unanimously adopted expressing appreciation of the work which is being done for the preservation of this portion of the South Australian fauna and flora.

Dr. F. Dixey gives an account of the preliminary results of his survey of the country to the north-west of Lake Nyasa in the *Nyasaland Times* of December 15, 1925. Attention was directed to this area by the discovery of fossil Dinosaur bones by Mr. Holt in a sterile wilderness which has remained little known as it is practically uninhabited. This country consists of ridges of the old crystalline rocks, which form the foundation of all this region, with sedimentary beds in the intervening valleys. Dr. Dixey has obtained from these beds a large collection of fossil Dinosaurs from a tract of country 80 miles in length. The beds extend across the Songwe River into Tanganyika Territory. They rest unconformably on the coal-bearing Karroo Beds of Mt. Waller, in which Dr. Dixey has discovered remains of large reptiles, which he describes as millions of years older than the Dinosaur beds. The Dinosaur beds pass eastward under the deposits of Lake Nyasa, which contain fossil shells similar to those still living in the lake. The lake beds occur in successive terraces, some of them hundreds of feet above the level of the lake. Their deposition was followed by volcanic eruptions, of which the line of hot springs that runs throughout Nyasaland represents the final stage. Dr. Dixey reports that this part of the floor of the Rift Valley has been lowered by faults in several stages, each accompanied by an increased tilt toward the north-east. Lake Nyasa originally occupied a small area near Florence Bay, and has increased to its present size by the continued subsidence of the floor of the Rift Valley. The discovery of these fossils represents a valuable contribution to the geology of Africa, for when determined they will give two well-established Mesozoic horizons in Nyasaland.

MR. T. A. JOYCE, Deputy-Keeper of the Department of Ceramics and Ethnography of the British Museum, sailed on February 6 for British Honduras, where he proposes to spend a period of four months in investigating the relics of ancient Maya civilisation. Mr. Joyce's work will be in continuation of the pioneer investigations of Lady Richmond Brown, Mr. F. A. Mitchell-Hedges and Dr. T. W. Gann, who have already spent two seasons on these sites. As the ruins are covered with forest growth, the work of these expeditions has been confined mainly to clearing away the jungle Evidence was, however, obtained of the existence of some remarkable buildings and of at least one structure of a type not known elsewhere in Central America. The masonry of the earlier work was of a higher character than the later This is fully in accord with what is known of the development of Maya culture in other parts of Central America. Nothing is at present known of the origin of these buildings, but the absence of defences would suggest that they were used for ceremonial purposes Mr. Joyce's special knowledge of American archæology should enable him to throw fresh light on the problems of Maya culture as a result of this expedition

EXCAVATIONS in Mesopotamia during the present season are proving highly successful, and the results of the expeditions now in the field, especially the Weld-Blundell Expedition, are likely to produce some remarkable results. At Kish, where the Weld-Blundell Expedition is at work, a number of complete early Sumerian skeletons have been obtained. These will provide valuable material for the elucidation of the physical characters of the early Sumerians and the obscure problem of their ethnological affinities, especially if this material should prove really comparable with the dozen or more skeletons of the Indo-Sumerian period, of which the discovery at Mohenjo-Daro in Sind is announced by the Indian Archæological Department Equally important is the announcement of the discovery of a complete series of perfect specimens of the early painted polychrome and monochrome Sumerian pottery with geometrical design. This is the first discovery of perfect specimens of this ware in any quantity, and places beyond dispute its connexion with the thin pottery of the first Susan period. The pictographic script discovered with the painted ware is the earliest yet known, dating from a period anterior to 3500 B C as a minimum

THE Frankfurt correspondent of the *Times* describes, in the issue for February 3, the position and prospects of the German chemical industry, and some of the efforts it is making to regain the supremacy it enjoyed before the War. Since the conclusion of peace, that industry has encountered a sea of troubles. Foreign countries have developed powerful industries of their own, and strong protective tariffs have been erected against German chemical products both in Europe and the United States Compared with the year 1913, external sales of German dyestuffs have decreased by 50 per cent. and of German fertilisers by more than 95 per cent. The United States now produces 90 per cent. of its requirements in dyestuffs, and Italy, which had practically no dye-making industry in 1913, about 60 per cent. Manufacturing profits in Germany have practically disappeared, loss of territory and raw materials, inflation and scarcity of capital, have combined to retard progress and expansion

IN spite of all this, however, Germany still leads, and is making stupendous efforts to recover her former position of undisputed supremacy in the chemical industry. Belief in the value of scientific research is as potent as ever. The *Interessengemeinschaft* (I G), which formerly dominated the production of dyestuffs in most countries, has nearly doubled its capital, and extended its influence in many ways. It has taken over control of the big nitrogen factories and is energetically developing foreign sales (German farmers now pay less for their fertilisers than in 1913), its technical efficiency, economic cohesion, and other factors make it the most powerful chemical organisation in the world. As in the past, this combination is pursuing an intensely nationalistic and aggressive chemical policy to secure the most effective working of foreign markets, its work is subdivided among groups, each of which is allotted a definite geographical sphere of influence. The South American markets have been recaptured, whilst those in Russia and south-eastern Europe have been nearly secured. Recent attempts to win over the Norwegian manufacturers have so far been unsuccessful, and the overtures to dyestuff producers in Great Britain and Japan are still proceeding.

THE eleventh annual report of the Committee for the Investigation of Atmospheric Pollution, for the year ending March 31, 1925, has recently been issued by the Meteorological Office, Air Ministry (M O. 280 · H M Stationery Office, 5*s* 6*d*. net) The results obtained for the year show that there are large areas of Great Britain which are not represented, but the Midland area, which suffers most from smoke pollution, is taking a very active interest in the investigation. The deposit of impurity is registered at forty-eight stations, the results are given for each month, also the summer total, winter total, and total for the year A comparison is made between the general average and the average at the same stations for the previous five years. The amount of rainfall is also given; the total was generally more than the average, while the deposit of tar was lower A series of maps shows the position of the gauges at the different stations, which in many cases offers considerable explanation of the results The automatic recorder for suspended impurity shows some very interesting results. For Blackburn, Stoke-on-Trent, and Westminster, curves are given showing the impurities for week days, Saturdays, and Sundays; the industrial and domestic smoke each has its say The smoke from chimneys is largely affected by the wind velocity and direction. Some results are also given of the observations made with the dust counter During the period of widespread fog in London between December 9 and 12, 1924, interesting observations were made in comparison with Cheam, 11 miles south-west of London; there was roughly fifty times as much impurity by weight in the London fog, while there was a much larger amount of water at Cheam. Often at Cheam the limit of visibility was less than in London

AMONG the anniversaries of scientific interest which occur this year is that of the bicentenary of the birth of John Anderson, for forty years professor of natural philosophy at Glasgow. The contemporary of Watt and Black, Anderson was the first university professor in Great Britain to step aside from the beaten track to give regular courses of scientific lectures to men engaged in practical pursuits Four days a week he lectured on physics illustrated by the aid of mathematics, but on Tuesdays and Thursdays the facts that were taken for granted in the other lectures were ascertained "by a direct appeal to the senses, or by stating the testimony of unexceptional authors, whilst the knowledge of these facts was shown to be of great advantage for the improvement of human nature and the progress of the useful and elegant arts" These ideas are set forth in his "Institutes of Physics," published in 1786. Ten years after the publication of this work, Anderson died leaving about 1000*l.* to be applied to the foundation of a university to bear his name. Though the sum was certainly too small to put his whole scheme into practice, a start was made; success was achieved from the first, and from the institution so founded sprang the mechanics institutions of the past and the technical colleges of to-day. Anderson's Institution, Anderson's University, or Anderson's College as it was known in the old days, is now the Royal Technical College of Glasgow, one of the most flourishing institutions of its kind. Anderson was born in 1726, but the exact day does not appear to be known.

AMONG the pioneers of Italian geology a prominent place must be given to Scipione Breislak, the centenary of whose death at Milan occurs on February 15. Born in Rome of Swedish parents, Breislak distinguished himself as a professor of physics and mathematics at Ragusa, and at a time when geology was in its infancy studied the rocks of the Papal States He was also employed by the King of Naples as an inspector of mines During the political upheaval due to the Napoleonic wars, he spent some years in Paris, but afterwards had an official appointment at a powder factory near Milan. His text-book "Introduction to Geology," which was published in 1811, contained an able criticism of the Neptunian dogmas, and did much to eradicate their teaching from the universities and colleges. Breislak was one of those who adopted Desmarest's views on the volcanic origin of basalt.

THE *Lancashire* (later *Lancashire and Cheshire*) *Naturalist* was founded by Mr. W. H. Western, of Darwen, in 1907, and he printed and published it for the common good until 1919. It was then taken over by a committee, and when three years later the committee found itself unable to continue, Mr Western resumed responsibility At the end of last year he found that he did not get the necessary support and was compelled to give it up—a decision which every one interested in the progress of natural knowledge will regret, for the paper has done splendid work in encouraging the examination of the local fauna. Fortunately, however, Mr. A. A Dallman (17 Mount Road, Higher Tranmere, Birkenhead) has come forward with a scheme for re-establishing the journal as the *North-Western Naturalist.* We hope he will receive the support he deserves. The active botanists and zoologists of the district will provide plenty of good material, and Mr. Dallman is anxious to hear from any one who is interested in the scheme, and especially from prospective subscribers and those who would be willing to help the paper over its first year or two by means of a guarantee.

THE arrangements for the Optical Convention, the meetings and exhibition of which will take place in the Imperial College of Science and Technology, South Kensington, during the week April 12-17, are now well advanced. An important part of the work of the Convention will be the exhibition, which is being arranged to be fully representative of British optical manufacture in all its branches Apart, however, from the commercial section of the exhibition, it is intended to have an Experimental and Research Section, to which it is hoped private individuals and research and teaching institutions will contribute. Those who have exhibits suitable for inclusion in this section are invited to communicate, not later than February 27, with the Secretary of the Optical Convention, 1926, 1 Lowther Gardens, Exhibition Road, London, S.W.7. A brief description of any exhibit accepted will be required, for inclusion in the catalogue. Those who wish to offer exhibits of historic interest should communicate with Mr. D. Baxandall, at the Science Museum, South Kensington, S.W.7, who is arranging the historical section.

THE Minister of Health, in conjunction with the Medical Research Council, has appointed a Committee to inquire and report from time to time, (1) on matters relating to the preparation, testing, and standardisation of vaccine lymph, (2) on practical methods of diminishing risks which may result from vaccination; (3) on the methods of vaccination which are most appropriate to give protection against risk of smallpox infection in epidemic and non-epidemic periods; and to co-ordinate the work on these questions in Great Britain and abroad. The Committee consists of: Sir Humphry Rolleston, Bart. (chairman), Dr F. R Blaxall, Dr G. F. Buchan, Dr. A E. Cope, Dr. Mervyn H. Gordon, Prof. J. C G. Ledingham, and Mr. J. R. Perdrau. The secretary of the Committee is Dr. J. R. Hutchinson, a medical officer of the Ministry of Health, Whitehall, S.W.1, to whom all communications should be addressed.

IN recent years the activities of the Optical Society have expanded in many directions in the field of optics, and the report of the Council of the Society presented at the annual general meeting of members on February 11 gives evidence of further development. During the past year the Council undertook the preliminary arrangements which resulted in the appointment of a representative committee to organise an optical convention in 1926. The formation of an Ophthalmological Section of the Society is now contemplated, and preliminary meetings devoted to the consideration of papers of an ophthalmological character have been arranged and have provided evidence of the increasing amount of scientific work that is being done in connexion with ophthalmological optics. In order to facilitate and extend the use of the decimal bibliographical classification of the Institut International de Bibliographie, a manual dealing with the application of that classification to optics, light and cognate subjects has been prepared and will shortly be published by the Society. The revenue accruing from the increased sales of the Society's Transactions has placed the finances of the Society in such a satisfactory position that the subscription payable by members has been substantially reduced and the entrance fee suspended

THE *Quarterly Review* for January (No. 487) contains an instructive article by Prof. J. Arthur Thomson entitled "Biology and Social Hygiene," the general moral of which is "that social organisation is not necessarily a good thing in itself. It requires to be scrutinised not only in terms of wealth and health, both so conspicuous in the bee-hive, but in terms of the higher values—the good, the beautiful, and the true, with their outcome in the evolution of man's personality." Prof. Thomson would recommend to the Ministry of Health the discovery and utilisation of outstandingly healthy men and women as missionaries of health, the revival in every town and village of a Beautifying Society, a more conscientious criticism of what we buy, more selection for health, and lastly, an order of merit for outstanding health! He pleads for more biology in education, so that pupils leaving school would be interested in the world without, both animate and inanimate. Lastly, on eugenics, child-breeding and rearing, some very sane opinions and conclusions are expressed on the controversial subject of birth control.

RECENT winter storms which have wrought so much destruction in the North Atlantic, including the loss of the *Antinoe*, the crew being rescued by the *President Roosevelt* on January 27 after four days struggle with the elements, and the *Laristan*, which sank on the same day after the rescue of six of her crew by the *Bremen*, are the subject of an article in the *Times* of February 6 by Sir Napier Shaw. The stormy period is likened to the winter of 1898–9, which was made the subject of a special inquiry by the Meteorological Office. Just twenty-seven years ago, considerable anxiety was caused by the delayed arrival of vessels overdue, including the Cunard Liner *Pavonia* and the Hamburg-Amerika ship *Bulgaria*. For this special inquiry, information had to be extracted from the logs of ships. To-day, observations transmitted by wireless are sufficient to give necessary details. The conditions are similar; the main feature is the belt of vigorous air current across the Atlantic nearly along the shipping lanes from west to east and on to the Scandinavian coast. The westerly winds are fed by a current from the cold north-west over Labrador and eastern Canada, and a feeder from Bermuda or from the Gulf of Mexico. One feeder is cold and dry, the other warm and moist; these throw the air of the North Atlantic into convulsions. A feature in both stormy periods referred to is the intense cold experienced in America on one side of the Atlantic, while on the other side, in Great Britain, the weather was unseasonably mild Sir Napier Shaw hints at certain calculations common to the two stormy periods, and concludes that we must expect still to find the Atlantic the scene of wrecks, unless we can develop still further our capacity to build invulnerable ships.

IN 1922 the Council of the British Psychological Society, at the request of the Educational Section of the Society, established a Committee for Research in Education. This Committee has now published a brief summary of its work in the past three and a half years. It has attempted to secure better understanding and closer co-operation between educationists and the research workers in the departments of psychology and education in our universities, and possibly its most important activities have been putting investigators into touch with those competent to give advice on particular research problems and advising and assisting heads of schools with regard to the use of mental tests. Periodic inquiries have been made as to researches bearing on education that are in progress, and summaries of the information so obtained are given in the *British Journal of Psychology*, Vol. 14, Part 4, and Vol. 15, Part 4. The place of psychology in the curriculum of training colleges formed the subject of another inquiry, and a summary of the detailed information received from sixty-three colleges was published in Vol. 2, No. 2, of the *Forum of Education*. Another side of the work of the Society, likely to grow both in amount and in importance, is international. In co-operation with the University of Toronto it is compiling a bibliography of mental tests published in England and, to assist the University of Iowa in an investigation of "arithmetical norms," it has secured "completed tests" from a number of schools in England.

THE French Association for the Advancement of Science will celebrate its jubilee this year at the annual meeting to be held at Lyons. An international Exhibition for the Advancement of Science, to include all branches of science and its applications, is being organised for July 24-August 1. M. Pilon, 23 rue Casimir Perier, Paris, has been appointed Commissaire Général of the Exhibition.

IT is announced that the first Federal Conference of Turcoman Educators will be held at Baku on February 20. The subjects will be the language, history, ethnography, and literature of the Tartar and Turcoman peoples, as well as Tartar and Turcoman education

Among those who have signified their intention to be present are Profs Oldenburg, Barthold, Marr and Pavlovitch. In this connexion it is interesting to note that a proposal has been mooted and favourably received at a meeting held on December 14 last, for the substitution of Latin characters in place of Arabic as the basis of a new Turcoman alphabet A committee of the Scientific Orientalists' Association has been formed to take steps to introduce the new alphabet.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A whole-time analytical chemist under the County Council of Dumfriesshire, as public analyst under the Sale of Food and Drugs Acts—The County Clerk, County Buildings, Dumfries (February 19). A Live Stock Officer under the Ministry of Agriculture and Fisheries—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S.W 1 (February 22) A laboratory assistant at the Building Research Station of the Department of Scientific and Industrial Research—The Director of Building Research, Building Research Station, Garston, near Watford (February 22). An assistant in the Technical Records Section of the Admiralty—The Secretary (C.E.), Admiralty, Whitehall, S.W.1 (February 22). An assistant curator in the Department of Antiquities and Anthropology of the Bristol Museum and Art Gallery—The Director (March 6). A lecturer in applied chemistry in the Manchester Municipal College of Technology—The Registrar (March 12). A professor of mathematics in the University College of North Wales, Bangor—The Registrar (March 20). An assistant (museums) at the Royal Botanic Gardens, Kew—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S W.1 (March 31) A calculator for the Royal Airship Works, Cardington, Bedford—The Director of Airship Development, Royal Airship Works, Cardington, Bedford. A junior assistant under the directorate of explosives research of the Research Department, Woolwich—The Chief Superintendent, Research Department, Woolwich, S.E 18

Our Astronomical Column.

COMETS —Dr. Baade detected Tuttle's periodic comet on January 12, 19^h U T in R.A. $22^h 27^m 52^s$, N Decl 40° 18′; the magnitude being 15·5. The daily motion is $+3\frac{1}{4}^m$, south 10′. The time of perihelion passage is deduced to be April 28·73 U.T., which is 1·08 days later than the ephemeris of Idelson and Musselius, 3·33 days earlier than that of Stobbe The period is 13·54 years, the last passage having been on October 28·543, 1912. The comet was seen at the returns of 1790, 1858, 1871, 1885, 1899, 1912 Its detection at the 1912 apparition was accidental, as no one had calculated the perturbations by Jupiter, which were large, so that it came two months before it was expected

It will probably be visible with moderate instruments on March 4-15, when the moon will be out of the way. In April it is too near the sun for convenient observation.

Mr. H E. Wood has sent a series of observations of Ensor's comet made by him at Johannesburg between December 14 and 21; from these Mr. G Merton and Dr. A. C. D. Crommelin have revised the orbit as follows:

T	1926 Feb 11·974 U.T
ω	354° 55′ 43″
Ω	282 26 56
i	123 1 5
log q	9·50852

EPHEMERIS FOR 6^h U.T.

	R A	Decl
Feb. 16.	20^h 56 0	10° 57′ S
,, 24.	20 52·0	3 47 N
Mar. 4.	21 2·8	21 4 N

The comet should be looked for in the east about dawn.

SOLAR RESEARCH AT MOUNT WILSON.—Since the publication in this journal (Supp, January 19, 1924) of a summary of the results obtained by Dr Hale and his colleagues from their comprehensive investigations in solar physics during the last seventeen years, a more detailed account of their observations and conclusions has been awaited with great interest. This is presented in the *Astrophysical Journal* for November 1925 (vol. 62, p. 270), and bears witness to the untiring skill of the Mount Wilson observers in their examination of 2200 spot groups for polarity and field-strength It would be out of place to attempt to give a summary of this paper, when it has been already more ably and completely given by Dr Hale himself in the supplement mentioned, to which reference should be made for further information It may be mentioned, however, that more details are given, both of the observations and of the results obtained, than in the previous account, while a revised scheme of classification into unipolar, bipolar, and complex groups, is fully described with various subdivisions

The nature of the hydrogen vortices, as shown by direction of whirl, is discussed in another paper by Dr. Hale (*Proc. Nat Acad. of Science*, November 1925). According to the electromagnetic theory of Stormer, these vortices are composed of charged particles constrained to move along the lines of force of the magnetic fields due to the spots beneath. The observations at Mount Wilson, however, show that the sign of the charge producing sunspot fields is invariable, a change of polarity being due to reversal of the direction of whirl. Change of polarity in the sunspot should produce a reversal of the direction of motion in the hydrogen vortices, according to the electromagnetic theory, but the observations do not confirm this, and Dr. Hale is led to the conclusion that the hydrogen vortices are purely hydrodynamical phenomena corresponding to terrestrial cyclones

ANOTHER ALGOL VARIABLE —In 1922, Miss Woods of Harvard College Observatory found that the star BD − 7° 5271 was faint on 6 plates out of 85 examined, and concluded that it was a variable, probably of the Algol type. Nothing more was published concerning the star for three years, Mr J. Witkowski of Cracow Observatory now publishes a series of observations ranging from July 30 to Oct. 30, 1925 (*Acta Astronomica*, Dec. 30, 1925). He confirms the type as being that of Algol The period is 2·1387 days, the light-range from 9·8 to 11·1 mag., and the duration of eclipse 6 hours The minimum is fairly sharp, and the light-curve symmetrical about it.

The position for 1925 0 is R.A. $20^h 18^m 12^s$, S Decl. 7° 35′·4, spectral type A 2.

The observations were made with a comet-seeker of $5\frac{1}{4}$ in aperture The star is thus within reach of observers with moderate equipment.

Research Items.

A Wood-carving from Easter Island.—In the *Museum Journal* (Philadelphia) for June last, which has recently been issued, Mr. H. U. Hall figures an example of that rare type of the so-called household gods of Easter Island which shows a combination of features of both human and animal forms. Five figures only of this type are mentioned in Dr. Brigham's survey of Polynesian material in museums, and three additional are known to have been at one time in the hands of private owners. The one here described by Mr. Hall is in the University Museum, Philadelphia. It represents a lizard-man, but it differs in detail from a similar lizard man formerly in the possession of Mr. J. Edge-Partington with which it is compared. The lower portion of the image ends in a rounded handle. The arms are brought together in the position of a suppliant. Other examples of these images are pierced with a hole to enable them to be carried strung on the person in procession, but this example, being some two feet long, was obviously carried by the handle, which shows signs of much use. Mr. Hall doubts whether it really represents a man-lizard. It may be an unconsciously anthropomorphised lizard. The lizard in Polynesia has a considerable prominence in magic and religion. Its appearance in Easter Island may be a memory of this prominence, or as an egg-producing animal it may have been regarded as a peculiarly effective mediator with the gods. This conception may have been helped by the prominent part played by the first egg of the season of a certain type of sea-fowl in the bird-man cult.

The Prehistoric Cultural Provinces of the Iberian Peninsula.—MM. Bosch-Gimpera and L. Pericot publish in *L'Anthropologie*, t. 35, Pts. 5-6, an important classification of the archæological remains of Spain and Portugal in the neolithic and æneolithic periods, by which they show that the Iberian Peninsula at these times can be divided up into a number of cultural provinces which persist into the Bronze Age, when they disappear, and do not appear again until the Iron Age. After briefly surveying the cultures of the palæolithic, epipalæolithic, and protoneolithic periods, which are derivative from the Franco-Cantabrian and the Capsian of the palæolithic, with an indigenous, but fully differentiated, culture on the Atlantic coast to be attributed to the influence of environmental changes, and an intrusive culture at Almeria, they distinguish four cultural provinces in the neolithic period: a western or Portuguese culture; a Central culture—this being a culture of special importance, of which the main characteristic is the highly decorated bell-beaker; the Almerian culture, and the Pyrenean culture. Each of these shows a continuous development with, however, certain advances and interactions except in the case of the Pyrenean culture, which apparently disappears for a time, possibly owing to failure to develop, but reappears in the æneolithic stage. At this period, indeed, it becomes sufficiently strong to force the retreat of the northernmost extension of the Almerian culture which had spread along the east coast of Spain at the beginning of the æneolithic period. The western culture is characterised in particular by the megalithic type of burial, and while in the earlier phases it was confined to Portugal, and in particular the north and centre, at a later stage, in the æneolithic period, it extended eastward and especially into Estramadura, Salamanca, and Huelva.

The Fishery of the Greenlanders.—In No. 7, *Meddelelser fra Kommissionen for Havundersøgelser Ser. Fiskeri*, Bind 7, Prof. Ad. S. Jensen gives a most interesting and well-illustrated account of the fisheries of Greenland. Dr. J. Schmidt in the preface points out that the author was leader of the fishery investigation expedition sent out by the Danish Government with the brig *Tjalfe* in 1908–9, and that many of the important observations regarding the Greenland Halibut made during those expeditions have been turned to practical use, proving a source of real profit to the Greenlanders. Several of those species which play a great part in the international fishery carried on in adjacent waters are almost, or entirely lacking in Greenland, the haddock for example, and the plaice and other flatfishes, with the exception of the halibut and Greenland Halibut. Prof. Jensen is inclined to believe that the stock of cod in Greenland is mainly recruited from elsewhere by immigration. He thus directs attention to an important problem which is also of interest in connexion with the Iceland investigations.

Hydrography of the English Channel.—In *Rapport Atlantique* 1924 (Conseil Permanent International pour l'Exploration de la Mer) Mr. H. W. Harvey, Hydrographer at the Marine Biological Laboratory, Plymouth, gives a useful summary of the results, and interpretations based upon them, which have been obtained by various workers who have studied the hydrography of the English Channel. An account of the extent of our present knowledge of the features of the water movements, and the variation of temperature and chemical composition of the sea water, is followed by a discussion of their biological significance. Two observations regarding the herring are of interest. A result of water movement in the English Channel is that herring spawned in the eastern end of the Channel are likely to be carried into the North Sea. A comparison between the mean weight of herring per landing by steam-drifters at Plymouth during the herring season—December and January—since 1921, and the temperature at a depth of 5 metres, shows that for four consecutive seasons the mean weight per landing has reached its seasonal maximum when the temperature has been between 10° C. and 11° C.

Corals and Zooxanthellæ.—Dr. H. Boschma, working on living material collected at the Bermuda Biological Station, records observations on the part played by unicellular algæ (zooxanthellæ) in the nutrition of corals (*Proc. Amer. Academy Arts and Sci.*, vol. 60, No. 9, Nov. 1925). Most of his experiments were carried out with Isophyllia, which has large polyps. The statements in the literature that the cœlenteron seldom contains food are based chiefly on the examination of preserved material, the polyps of which have discharged the contents of the cœlenteron owing to the strong contraction which takes place on preservation. Under normal conditions, the food of the polyps consists chiefly of the algæ which are living in its endoderm cells—and in freshly collected specimens algæ are always present in the mesenterial filaments, small planktonic organisms are also captured and digested, but under normal conditions these are too scanty to serve as the sole nutriment of the polyps. When the digestive organs (the mesenterial filaments) can obtain sufficient food from other sources—as in examples fed in the laboratory with mussel—they do not ingest zooxanthellæ. The algæ which were present in the filaments are completely digested, so that after abundant feeding on mussel, the mesenterial filaments may become totally devoid of zooxanthellæ. The symbiotic algæ are ingested only when other food is scarce, and to this extent the polyps are parasitic on the algæ. In other Bermudian Anthozoa the zooxanthellæ form a large part of the food supply of the polyps. In a further paper (*Biol. Bull.*, Dec. 1925) the author states that in Astrangia also the zooxanthellæ furnish part of the normal food of the polyps, and that polyps which have no zooxanthellæ can be easily infected by feeding them with crab meat mixed with parts of the tissues of strongly infected polyps.

THE FLORA OF JUAN FERNANDEZ AND HAWAII.—Prof. Carl Skottsberg, Director of the Botanical Garden at Gothenburg, Sweden, was Bishop Museum Fellow in Yale University for 1922–23; and as a result there is published as *Bulletin 16 of the Bishop Museum*, Honolulu, a very interesting phytogeographical discussion of the flora of the islands of Juan Fernandez and Hawaii. Both are groups of volcanic islands, very remote from each other, but with common features in their flora. Prof. Skottsberg considers that they are young islands of which the flora contains many isolated types, the result of isolation of considerable age, and of geographic changes. The high endemism, he concludes, is scarcely likely to be due to the extermination in all other countries of identical or closely allied species. There is evidence in favour of a continental origin of the Juan Fernandez flora; that it existed before the present islands were formed, and took possession of them during the submergence of its old home. Part of this flora he derives from the Antarctic continent, but by way of South America rather than by a direct land bridge. Hawaii also contains old Pacific and Antarctic types, but the road from Polynesia to Hawaii is more difficult to trace. However, the author is confident that the history of the Hawaiian flora is in main outline similar to that of Juan Fernandez. Another general conclusion is that the disappearance of the Tertiary Antarctic flora during the Ice Age is of fundamental importance and has been greatly underrated by plant-geographers. "No catastrophe of such dimensions and of such consequences has ever befallen the Tertiary flora of the Northern Hemisphere." The Bishop Museum Yale Fellow for 1921–22, Prof. F. L. Stevens, of Illinois, gives a full list of the fungi known to exist in the Hawaiian islands as *Bulletin No. 19 of the Bishop Museum*. Most of these are from collections made by himself in 1921, but all other available collections and lists are included; rusts, smuts and parasitic fungi have been more thoroughly collected, higher fungi and fleshy Agarics only taken incidentally.

TCHEVKINITE AND AFFINITIES OF TRILOBITES.—A series of eight papers in Russian, French, German or English, and an appendix containing abstracts of recent non-Russian scientific literature appears in the *Bulletin of the Russian Academy of Sciences*, Series 6, Nos. 12-18, 1924. Three papers, in Russian, by Boldyrev, Kaufman and Kryzanovskii describe the rare mineral tchevkinite, which is a titanosilicate of cerium, lanthanum and other metals, from the Ilmen Mountains. The mineral was originally regarded as an amorphous alteration product; some Russian crystals have now been thoroughly investigated and are found to be monoclinic, confirming the doubtful suggestion by Prof. Lacroix from Madagascan specimens. In a discussion, in English, of the relations of the trilobites by Fedotov, many of Walcot's genera are rejected as based on inadequate material, and the author concludes that the trilobites, though closely akin to the Crustacea, are an independent group ancestral to the arachnids. Nasonov describes the general distribution of the *Turbellaria rhabdocoelida* in European Russia.

POST-EOCENE MOLLUSCA OF NORTH-WESTERN INDIA.—The late Dr. Vredenburg, to whose four excellent memoirs on the Indian Tertiary gastropoda we directed attention in these pages (NATURE, May 6, 1922, p. 594, and August 25, 1923, p. 294), had at the time of his lamented death in March 1923 just completed the proofs of the memoir now before us. This "Description of Mollusca from the Post-Eocene Tertiary Formations of North-Western India" has now been issued by the Geological Survey of India (*Memoirs*, vol. 50, pt. 1). The forms dealt with were obtained from the stratigraphical division distinguished by Blanford as the Nari, Gáj and Mekran. The detailed study of these fossils has revealed the existence of many species already known either from Europe or from the East-Indian archipelago. A widespread temporary oceanic connexion established by the great marine oceanic transgression of the Oligocene, undoubtedly accounts for the mingling of eastern and western forms at this horizon. Some 150 species, a large proportion of which are new, are fully and carefully described in this ample memoir, and many of these are illustrated on 13 plates from photographs taken by the author himself, whose demise is assuredly a great loss to palæontology.

ISOSTASY IN THE SOUTHERN PACIFIC.—In the *Journ. Wash. Acad. Sci.* for December 4, William Bowie gives the results of an isostatic reduction of gravity determinations at five island stations in the Southern Pacific. Assuming a depth of compensation of 96 km., the isostatic anomalies that remain vary from +0·003 dyne to +0·061 dyne, the average being 0·033 dyne against an average free-air anomaly of 0·130 dyne. The theory of isostasy thus reduces the difference between observed and calculated values by 75 per cent. In explanation of the rather high anomalies that still remain, Bowie considers that in part they may be due to errors in the observations, the possible inaccuracy being so high as 0·010 dyne, but that a more important cause of divergence is a probable excess of density in the rocks underlying the islands. In the calculations the rock density is taken as 2·7, which, according to Washington's figures, is undoubtedly too low. By taking the density as 3·0 the average anomaly is reduced by about a half. The evidence is thus in close accord with that of land-data and supports the assumption that the earth's crust under the oceans is in an isostatic condition.

TIDAL FORCES AND CONTINENTAL DRIFT.—At the annual meeting of the Geological Society of America held during last December, F. B. Taylor, who anticipated Wegener in an hypothesis of continental drift, read a paper in which he advocates a remarkable theory of the origin of the moon. He considers that the Tertiary mountain ranges were raised as a result of the horizontal sliding of continental blocks towards the equator; that the evidence strongly points to an external cause for the movement; and that tidal forces are therefore the only causes to which adequate appeal can reasonably be made. Solar tidal forces alone are held responsible for the older mountain ranges. Near the close of the Cretaceous, however, a sudden and strongly-marked increase of crustal movements began, and has continued with diminishing energy down to the present day. There is no way of explaining this world-wide increase, according to Taylor, without assuming a corresponding increase in tidal force, and this assumption involves the acquisition by the earth of a body like our present moon and its permanent retention as a satellite. The implied capture theory of the moon is stated to be sound from the astronomical point of view. With regard to mountain building, Taylor's views are not likely to meet with acceptance. The moon's tidal force is approximately 215 times more powerful than the present solar tidal force, and there is certainly no geological evidence to suggest that the Alpine-Himalyan mountains are the result of forces 216 times as great as those which produced the Armorican, Caledonian, and older mountain systems The recent work of Joly and Holmes, to which Taylor makes no reference, shows that no theory of crustal movements can possibly be complete which ignores the almost incredible forces set up as a result of the liberation of energy from radioactive elements. Here we have an indubitable cause of mobility permitting conditions in which tidal forces can become effective, and involving no such gratuitous assumption as the capture of the moon in Cretaceous times

SUPERFICIAL SOLUTIONS, OR TWO DIMENSIONAL FLUIDS —M A Marcelin, in the *Annales de Physique* for November-December, deals with the thin films formed by certain oils on the surface of water from a new point of view. It has been supposed that the extension of the surface of the oil could go on until a layer of molecules was formed which were in contact with one another at their sides, and that if the amount of oil for a given surface was too small to cover it with such a layer, no change took place in the surface tension. Using, however, two-dimensional floating apparatus, cut out of paraffined mica, and representing pumps with valves and pistons, the author has been able to show that the surface tension is lowered for very much smaller amounts of oil than the above. If the amount of lowering is regarded as the "surface pressure," p, a law holds similar to that of Boyle and Mariotte for gases, $pS = \text{constant}$, where S is the surface This is true up to about twenty-eight times the surface occupied by the oil in a monomolecular layer, with all its molecules in contact with one another, a state which corresponds to that of a saturated vapour. M. Delaplace has found that Gay Lussac's law applies to these superficial solutions between 15° and 27° C., so that $pS = KT$, where K is a constant characteristic of the floating molecule, and probably also depending on the liquid on which it floats

INTERFERENCE BANDS —In the October and November issues of the *Journal de Physique*, M F. Wolfers describes a new system of interference bands he has discovered in the penumbra cast by the edge of an opaque screen when illuminated by a source of considerable dimensions. The best arrangement for observing them is a narrow horizontal slit illuminating a steel ball about 1 cm in diameter, and behind the ball a fine grained photographic plate. Along a horizontal diameter the light, instead of falling off gradually from the edge of the penumbra to that of the umbra according to the ordinary theory of diffraction, is found to show three or four bands the intensity of which is greatest near the edge of umbra. Their positions are independent of the nature, dimensions, and form of the source and screen and of the nature of the surface of the latter, nor does the light from them show any signs of polarisation. Their positions in terms of the wave-length of the light used, and the distances of the screen from the source and photographic plate, lead the author to conclude that they are due to interference of light coming from that part of the source which determines the edge of the umbra with light coming from the edge of the screen where it has been absorbed and emitted in quanta.

PHOTOGRAPHING THE INNER SURFACE OF A RIFLE BARREL.—The difficulties of inspecting and photographing the inner surface of a rifle barrel with a length of about 700 mm. and an internal diameter of about 6 mm have been ingeniously overcome by Mr. Seiji Nakamura, of the Physical Laboratory of the Tokyo Imperial University, by the construction of an instrument called a "solenoscope" (*British Journal of Photography*, 1926, p. 19). The final form of this instrument is a steel tube about 750 mm long and 6 mm external diameter, which has at one end a larger brass tube in which the eyepiece slides, and carries at the other end a microscope objective formed of two simple lenses, achromatism being found unnecessary. The eyepiece is an orthoscopic magnifier of Zeiss of 18 mm. focal length, and at the other end, beyond the objective, is a small 3-volt electric lamp. In order to get the image through so long and narrow a tube, five achromatic cemented doublets of about 68 mm. focal length are placed at a distance apart equal to twice the focal length of each Thus the image formed by the first is reproduced by the third (inverted) and again by the fifth (erect), and so viewed or photographed through the eyepiece. The second and fourth lenses act as condensers to avoid loss of light and are fixed where the two middle images are formed, but slightly removed from these positions to avoid the image of dust, etc, on their surfaces appearing in the final image. The resulting image is an evenly illuminated annulus which represents a short length (or ring) of the barrel. The paper is illustrated and has a photograph of a new barrel and one of a much-used barrel, which clearly demonstrate the efficacy of the instrument.

TRINITRIDE AND CYANATE IONS.—Experiments on the X-ray spectra of trinitrides (hydrazoates) and potassium cyanate made by S. B. Hendricks and L Pauling show that the trinitride and cyanate ions have closely similar configurations. An interesting result of the work, which is described in the issue for December 1925 of the *Journal of the American Chemical Society*, is that the trinitride ion is shown not to have a ring structure but to contain three nitrogen atoms in line (as in Thiele's formula)

RESISTANCE THERMOMETERS AT LOW TEMPERATURES —Some experiments by A G Loomis and J. E. Walters are described in the issue for December 1925 of the *Journal of the American Chemical Society* which were intended to test the applicability of platinum resistance thermometry to -193° Four platinum thermometers of the flat-coil type showed close agreement between observed and calculated resistances at the carbon dioxide point, and the flat coil types could, when properly constructed, be used at low temperatures and calibrated in the same manner as the strain-free types investigated by the Reichsanstalt and the Bureau of Standards

PARTIAL PRESSURES OF WATER VAPOUR AND SULPHURIC ACID —The December issue of the *Journal of the Chemical Society* contains an account of the investigation of the partial pressures of water vapour and sulphuric acid vapour over concentrated solutions of sulphuric acid at high temperatures, by J. S Thomas and W. F Barker. Air was passed through the acid and the saturated air passed to absorbing vessels. The results apply to sulphuric acid of concentrations between 89·25 and 99·23 per cent, and temperatures from 180° to 295°. It was not possible to take account of dissociation . figures are given on the assumption that the acid is not dissociated and another set on the assumption that it is completely dissociated. The results should be useful in connexion with large scale concentration apparatus

The Control of Insect Pests in Agriculture.

THE completion of the Ministry of Agriculture scheme for the appointment of advisory entomologists in each of the fourteen agricultural provinces of England and Wales has recently been fulfilled By means of this organisation, the Phytopathological Branch of the Ministry is now enabled to keep in touch from year to year with most parts of the country with regard to the incidence of insect pests. Each advisory entomologist has his headquarters in a collegiate or university centre in his province, and his field of work lies in the diagnosis of injury due to insect pests on behalf of the farmers and growers of that area, he is further concerned with the dissemination of useful information on such subjects, and in the carrying out of experiments on the practical control of pests of local importance At present the advisors' duties are therefore of a somewhat comprehensive character As time goes on, it is reasonable to hope that as the county councils' staffs develop and extend their spheres of utility, they will be able to take on much of the purely advisory duties. In this way it should eventually be possible to free the advisor in order that he may be able to devote his inquiries more especially to the investigation of particular local problems

The work of the advisors renders them in a position to forward to the Ministry annotated lists, or in some cases more detailed information, respecting the pests that come under their notice There is also a considerable number of voluntary observers located in different parts of England and Wales who assist in a similar manner The information thus garnered is collated and sifted in the Ministry's Pathological Laboratory at Harpenden The present report[1] is to a large extent a summary of the data collected by some sixty-two observers during the years 1922–1924 It is the fifth of its series, but differs from its predecessors in that tabular lists of every recorded species of injurious insect are, very wisely, no longer included Certain innovations in regard to pest control during the years under review are mentioned Perhaps the most notable of these is the application of certain proprietary compounds, collectively known as "carbolineum," as washes for fruit trees These compounds consist of various products obtained in the distillation of coal and are of variable composition There appears to be no question as to the efficiency of certain of the "brands" bearing the name of carbolineum in the destruction of the resting eggs of aphids and apple sucker It is important to know, however, whether such treatment can be carried out over successive years without injury to the trees; also, whether the manufacturing firms are able to give guarantees to the effect that materials which gave good results one year will remain purchasable with their original composition unaltered

Among individual pests the raspberry beetle has always been troublesome to raspberry growers and has also become a menace to loganberry culture Experiments carried out at the Long Ashton station show that it can be largely controlled by spraying the plants with lead arsenate when they are one-third, two-thirds, and fully in bloom Apart from the possibility of poisoning trees, the market price of the fruit in relation to the costs of spraying will be the deciding factor for, or against, this method of treatment. The apple blossom weevil is another insect difficult to control, and this fact has attracted attention at the East Malling Research Station, where the respective values of different methods of repression have been tested over the period 1921–1924 The only method that proved of value was the trapping of the weevils by means of bands of sacking tied around the trunks of the trees The hibernating weevils lay up in such material, which led to their capture in large numbers Among other noteworthy measures, the application of lime-sulphur against the "big-bud" disease of black currants has given promise when applied at winter strength in March

The control of vegetable root flies, which is occupying the attention of Mr K M Smith at Manchester, appears to be best achieved by the use of odorous substances acting as deterrents, which protect the crop by keeping the insects away One of the best of these preventives is stated to be anthracene oil absorbed in some powder carrier, such as powdered chalk. As the result of Lloyd's work at the Lea Valley Experiment Station at Cheshunt, on fumigation with tetrachlorethane, fumigants of this type have come into prominence in the case of White Fly attacks on plants under glass The application of tetrachlorethane is more expensive than that of hydrocyanic acid gas, but it is a less poisonous remedy for operatives to handle and, in the case of tomatoes, it is no longer necessary to dry off the house prior to treatment in order to avoid injury

The British Isles have up to the present suffered very little from the attacks of imported agricultural pests The factors contributing to this situation are not easy to discover, but the absence of extensive areas of country devoted to single-crop cultivation, together with the practice of crop rotation, afford conditions on the whole unfavourable to the establishment of immigrant forms Furthermore, a variable and, on the whole, inclement climate is probably an important barrier to most species which are denizens of warmer regions. Legislation also serves to keep down the number of alien species which reach this country. On the other hand, sundry foreign insects do succeed in gaining entry and, unless track is kept of them, it is possible that one or other kind may succeed in gaining a permanent foothold During the period covered by the present report several of such species are specially mentioned The most important of these is the Potato Moth (*Phthorimaea operculella* Zell), which has been detected by the Ministry's inspectors in consignments of potatoes imported from Malta and the Canary Isles Since it is an insect with considerable power of adaptation to climatic conditions, the destruction, or re-exportation, of such consignments is a very necessary measure Among other interceptions, larvæ of a beetle of the genus Brachycerus have occurred in consignments of snowdrop bulbs from Smyrna; beans affected by the American Bean Beetle (*Bruchus obtectus* Say) from Minnesota; and peaches from S Africa infested with larvæ of the Mediterranean Fruit Fly (*Ceratitis capitata* Wied)

The outstanding features during the period under review were. (1) the damage occasioned by Fruit Fly and to a lesser degree by Gout Fly in 1922, (2) severe outbreaks of aphids and caterpillars in orchards in 1923, (3) a remarkable absence of most epidemic pests in 1924 In each case the phenomenon observed appears to be largely fostered by the prevailing weather conditions during the seasons concerned, but, until we are in a position to correlate a larger number of years' observations between weather and fluctuations of pest epidemics, such conclusions are necessarily somewhat speculative

Several indigenous species of insects are, for the first time, recorded as injuring crops in England and Wales These include the fly *Chortophila sepia* Mg which did considerable damage to wheat in Cambridgeshire; barley and other cereals in Kent were attacked by the small acalypterate fly, *Diplotoxa limbata* Meig.; old potato sets in N. Wales were infested by a little-known Coccid, *Pseudococcus gahani* Green; in widely separated localities beans suffered from the attacks of several species of root flies of the genus Chortophila and, in Norfolk, the Dock Saw Fly (*Taxonus glabratus*) occasioned considerable injury to apples.

---

[1] "Report on the Occurrence of Insect Pests on Crops in England and Wales, for the Years 1922, 1923, and 1924" Miscellaneous Publications, No. 49, Ministry of Agriculture and Fisheries, 1925. 1s. 6d net.

Mr J. C. F. Fryer, the Director of the Ministry's Pathological Laboratory, has produced a report which summarises the activities of his charge in a concise and readable form. The value of documents of this character is usually not immediate, but it is rather that they place on permanent record information for the use of posterity.

A. D. IMMS.

Recent Star Catalogues.

A VERY interesting star catalogue has lately been published in the joint names of Prof. Frank Schlesinger and Ida Barney. It contains 8359 stars between N. Decl 50° and 55°, observed by photography at Allegheny Observatory between August 31, 1915, and July 14, 1916. The number of plates is ninety, their centres all being at Decl. 52½°, and the Right Ascensions increasing by 16 min, or 2·4° of great circle. The measured portion of each plate is a square 5° × 5°: each star appears on two plates; on one to the east of the centre, on the other to the west. The two plates are measured in reversed positions in the micrometer, so that all systematic "magnitude-equation" in R.A. should be eliminated. The object glass is a symmetrical doublet of four lenses, of aperture 103 mm., and equivalent focal length 1·635 metre, giving a scale of 126·2″ = 1 mm A circular stop ensures full illumination over the plate, but reduces the effective aperture to 75·5 mm. Exposure of 25 minutes is found to give strong images to well below the ninth magnitude, except in the case of some red stars.

The places given are referred to those of 1070 stars in the zone, which were observed (each star twice) on the meridian by Prof. R. H. Tucker at Lick Observatory from February 1917 to March 1918. Their places for 1917·0 are given as a supplement to this catalogue. Their average magnitude is 8·5, the same as that of the main catalogue. The latter is referred to the equinox of 1875·0, to facilitate comparison with the Harvard A G. Catalogue of the same zone. This comparison gives determinations of proper motion of all the stars They are printed to the third decimal of 1″, the probable error of each being about 0·015″.

On plotting the "crude" proper motions in R A. for the separate magnitudes and the separate hours of R.A., they form sine-curves the amplitudes of which steadily diminish for the fainter stars owing to greater distance, and the median lines of which get steadily lower. The latter result is due to "magnitude-equation" in the Harvard A.G. Catalogue. The values found for the latter increase from 0·039 s. for magnitude 6·4 to 0·232 s. for magnitude 9·7; these are applied in forming the printed proper motions.

It is welcome news that the zone from Decl. 2° south to 2° north, photographed about 1916, will shortly be published, and that Prof. Schlesinger contemplates the production of similar catalogues for all the A.G. zones.

Volumes 1 and 2 of the Sydney Astrographic Catalogue have lately come to hand. They cover Decl 51° to 53° south, and R.A. 0h to 6h and 6h to 12h respectively. Vol. 3 appeared earlier. It will need fifty-two volumes to cover the entire Sydney zone, which extends from 51° to 65° south The X, Y co-ordinates are printed to the third decimal of a reseau interval; the magnitudes are indicated by letters or numbers on two arbitrary scales, further information is needed to reduce these to the ordinary system. There are 280 stars on a fully printed page (but there are many gaps). Vol. 1 has 25 pages; vol. 2 (the galactic latitude of which is lower) 85 pages.

Explorations in Borneo.

THE fourteenth and fifteenth reports on the Sarawak Museum deal with the years 1915 to 1924. For most of this time it had no curator. Major J. C. Moulton left to join his regiment in February 1915, and his successor, Dr. E. Mjöberg, did not take office until May 1922 He in turn left in December 1924, and was succeeded in February 1925 by Mr. E. Banks. During his curatorship Dr. Mjoberg devoted his energies mainly to collecting, and these two reports give the chief results of his expeditions, of which the chief were those to Mt. Murud and Mt. Poi

Mt Murud had never been visited by a white man, and its precise position was in fact uncertain. It forms the most northern and highest point of the Pamabo Range, which here falls down into a deep valley, bounded by the east-west mountain range Batu Litan. Its height, estimated at 10,000 feet, proves to be 7200 feet, with another peak of 7160 feet. The mountain is built of sandstone, and its slopes are exceedingly rough, full of caves, holes, and crevices, and covered with enormous boulders. The natural difficulties of travel were not lessened by the difficulty of obtaining carriers, owing to the prevalence of an epidemic, and by the inability of the Dyaks to stand the climate of the heights Dr Mjöberg slept for six nights alone on the top ridge, making a proper biological survey. He describes it as "a strange-looking alpine region, with scanty low bushes of leathery appearance, covered with the yellow blossoms of a little epiphytic orchid. Here and there patches of smaller pine trees were seen. Bright scarlet or white flowers of the rhododendron and similar plant types were met with everywhere. Gigantic pitcher-plants (Nepenthes) of strange shape and countless varieties of beautiful, flowering orchids, formed the more striking types of plant life. Only a single little yellow-breasted bird broke the silence of this unknown landscape, never before seen by human eye"

The pitcher-plants just mentioned were responsible for the abundance of a very small frog In the absence of pools, these frogs lay their eggs in the pitchers, and being thus dependent on a minimum of water for passing through their larval stages, they cannot grow larger than one's thumb-nail

Strong lanterns of 250 candle-power were kept alight all night on the summit and attracted many curious moths and other insects. On the highest peak fresh tracks of the wild pig, *Sus barbatus*, were observed.

Descending to the plains of the Kalabit country, and along the Baram River, which was found to have its source on Mt. Murud, Dr. Mjoberg found that the natives of the main plateau had snared for him no less than ten complete specimens of the long-sought Bornean badger.

Of the other expeditions undertaken by Dr. Mjoberg, we need mention only that to Mt. Poi, where he thoroughly surveyed the region above 3500 feet, the highest peak reaching 5600 feet. Here, at heights between 3000 and 3500 feet, were found specimens of the primitive arthropod Peripatus, previously unknown from Borneo. They are comparatively flat and large, and may represent a new species or one of the forms previously known from the Malay Peninsula.

The large collections made by Dr. Mjoberg were distributed by him to such specialists as he could find to undertake the work of determination, but specialists are still required for very many groups, especially among Arachnida, Hymenoptera, Neuroptera, and Pseudoneuroptera.

University and Educational Intelligence.

BIRMINGHAM.—The following appointments have been made: Dr. William H. Wynn, Physician to the General Hospital, Birmingham, to be joint professor of medicine in succession to the late Prof. J. W. Russell; Mr. L. G. A. Sims to be lecturer in electrical engineering in succession to Dr. Randall, who has been appointed to a chair at Johannesburg.

The title of emeritus professor is to be conferred on Sir John Cadman, lately professor of mining, on his resigning his appointment as honorary professor and adviser to the Mining Department.

The following gifts have been received: A legacy of 100*l*. from the late Prof J. W. Russell; a scholarship of 60*l*. per annum from the British Burmah Petroleum Co. for students in the Oil Engineering and Refining Department; valuable models from the Mining Association of Great Britain; and a special weighing machine for the Fuel Treatment Laboratory of the Mining Department from Messrs. W. and T. Avery.

CAMBRIDGE.—The council of the senate has brought forward amendments to the general regulations for prizes and medals, it is proposed that in future, students shall not be permitted to use the same research work for obtaining a research degree and a university prize or medal. As matters stand, the student who has graduated at Cambridge is at a disadvantage when competing with a research student coming from another university; the former has to do three or four years' work before he begins his research, whilst the latter begins on arrival. The regulations for most prizes ordain that candidates must not be of more than a certain number of terms' standing.

OXFORD.—On February 2, Convocation confirmed a decree authorising a special allowance of 200*l*. a year, in addition to his ordinary stipend, to each professor being the head of a scientific department.

Active preparations are going on for the forthcoming visit of the British Association to Oxford on August 4-11.

There will be an election at Keble College, on March 15, to natural science scholarships, one on the Gibbs Foundation and one on the Field-Marshal Gomm Foundation, of the value of 80*l*. per annum. This sum is augmented by the College in the case of the former to 100*l*. per annum. Candidates will be eligible for these scholarships who have not exceeded the age of twenty years on March 15. Inquiries should be addressed to Mr. G. D. Parkes, Keble College. Intending candidates are requested to communicate their names and subjects on or before Saturday, February 24.

THE Committee of Award of the Commonwealth Fund Fellowships announces that applications must reach the Secretary, 50 Russell Square, on or before February 20. The fellowships will normally be tenable at an approved American university for two years. They are open to persons of British birth domiciled in England, Scotland, Wales, and Ireland who are graduates of recognised universities, are unmarried, and not more than thirty years of age. Women as well as men may apply. Provision amounting approximately to 600*l*. per annum will be made for the total expenditure involved during the tenure of a fellowship.

IN our issue of January 30, p. 178, reference was made to the lack of support which is hampering the development of the Imperial College of Tropical Agriculture, Trinidad. It is gratifying to learn from the reply given to a question asked in the House of Commons on February 8 that it has been decided to make a capital contribution of 15,000*l*. towards the cost of the erection of a hostel, a contribution of 3000*l*. towards the general expenses of the College in 1926–27, and, if absolutely necessary, certain further contributions in the three following years.

A THERESA Seessel Research Fellowship, for the promotion of original research in biological studies, is offered by Yale University. The value is 1500 dollars, and preference will be given to candidates who have already obtained their doctorate, and have demonstrated by their work fitness to carry on successfully original research of a high order. The holder must reside in New Haven during the college year, October to June. Applications should be made to the Dean of the Graduate School, New Haven, Conn., U.S.A., before April 1 next, and should be accompanied by reprints of scientific publications, letters of recommendation, and a statement of the particular problem which the candidate expects to investigate

FROM Manchester we have received a pamphlet by Mr. Spurley Hey, the Director of Education, entitled "Value for Money in Education." The gist of this answer to a call for economy in public expenditure on education is that whilst outlay can be stated in cash, the returns which the country is getting for the money spent on education cannot, that the expenditure is bound to increase still further, and that tax- and rate-payers had better pay up and look cheerful instead of criticising what they do not understand and cannot check. Manchester "business men" appear to have made unreasonable demands of the elementary schools: a "special type of arithmetical calculation" or "intimate knowledge of the geography of parts of the world with which their business is connected," or knowledge of foreign languages or shorthand or typewriting. Criticism based on such demands deserves the censure which Mr. Hey administers, but the pamphlet throws little light on such questions as: What, precisely, are the returns, admittedly not estimable in cash, which the administrators of education in Manchester aim at? Is the adjustment of means to ends demonstrably appropriate? And what evidence is there that the returns aimed at are, in fact, being produced?

Contemporary Birthdays.

February 11, 1847. Dr. Thomas Alva Edison
February 11, 1868. Prof. R J Durley, M.Inst.C.E.
February 12, 1872. Prof. A J. Ewart, F.R S.
February 13, 1843. Sir Thomas H. Holdich, K.C M.G.
February 15, 1861. Prof. A. N. Whitehead, F R S
February 16, 1848. Prof. Hugo De Vries, For. Mem R S

Dr. Thomas A Edison was born at Milan, Erie Co, Ohio He began life with scant educational advantages, and these, such as they were, came mainly from his mother's lessons (she was of Scotch descent) and his own omnivorous reading. Early in life he learnt telegraphy, and commenced experimenting in that department and in chemistry and electrical science. He invented the quadruplex and sextuplex telegraphic systems of transmission, the incandescent electric lamp, the phonograph, and a host of devices and appliances which have uses in the daily life of the peoples of all countries. He is a Commander of the Legion of Honour. During the whole of the War period he was engaged in work for the United States Government.

Prof. R J. Durley occupied the chair of mechanical engineering, McGill University, Montreal, 1901–12 He is now a consulting engineer in that city, and secretary of the Engineering Institute of Canada, Montreal. Educated at Bedford Modern School, he studied at University College, Bristol, and afterwards at University College, London. Apprenticed to Earle's Shipbuilding and Engineering Co, Hull, he afterwards became lecturer in mechanical engineering at the Municipal Technical School, Hull He is the author of "Kinematics of Machines" (1908) and of many technical papers.

Prof A J. Ewart, of the University of Melbourne, who occupies there the chair of botany and plant physiology, is a Liverpool man, and was sometime a demonstrator of botany in the university of that city before he graduated at Oxford. Formerly he was well known in various centres in Birmingham as a lecturer and research worker in botanical subjects.

Sir Thomas H. Holdich, traveller and mountaineer, was born at Dingley, Hampshire. He was educated at Godolphin Grammar School and Woolwich Academy, joining the Royal Engineers in 1862 An epitome of much of his career was reflected in 1887 by the award of the Royal Geographical Society's Founders Medal, allotted in consideration of services rendered in carrying out surveys in Afghanistan, also (1884–86) with the Russo-Afghan Boundary Commission, when he conducted operations over an area of 100,000 square miles He was the first Englishman to ascend the Paghmán Range, which lies between Kabul and the passes of the Hindu-Kush. Sir Thomas has consistently upheld the great traditions of the corps of Royal Engineers.

Prof. A N. Whitehead was educated at Sherborne School and Trinity College, Cambridge. Formerly professor of applied mathematics at the Imperial College of Science, South Kensington, he took up in 1924 the post of professor of philosophy at Harvard University, U S A. He was joint author, with the Hon. Bertrand Russell, of that work of fundamental issues, "Principia Mathematica."

Prof. Hugo De Vries, emeritus professor of botany in the University of Amsterdam, was born at Haarlem. He is a foreign member of the Royal Society and the Linnean Society, and Darwin medallist of the former.
